

Fault-Protected, Low-Voltage, Quad SPST Analog Switches

ABSOLUTE MAXIMUM RATINGS

V+	-0.3V to +13V
V-	-13V to +0.3V
V+ to V-	-0.3V to +13V
IN	(V- + 12V) to (V- - 0.3V)
COM ₋ (Note 1)	(V- - 0.3V) to (V+ + 0.3V)
NO ₋ , NC ₋ (Note 2)	(V+ - 12V) to (V- + 12V)
Continuous Current into Any Terminal	±40mA
Peak Current, into Any Terminal (pulsed at 1ms, 10% duty cycle)	±70mA

Continuous Power Dissipation (T _A = +70°C)	
16-Pin TSSOP (derate 5.70mW/°C above +70°C)	457mW
16-Pin Narrow SO (derate 8.70mW/°C above +70°C)	696mW
16-Pin Plastic Dip (derate 10.53mW/°C above +70°C)	842mW
Operating Temperature Ranges	
MAX471_C_E	0°C to +70°C
MAX471_E_E	-40°C to +85°C
Junction Temperature	+150°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature (soldering, 10s)	+300°C

Note 1: COM₋ pin is not fault-protected. Signals on COM₋ exceeding V+ or V- are clamped by internal diodes. Limit forward diode current to maximum current rating.

Note 2: NO₋ and NC₋ pins are fault-protected. Signals on NO₋ or NC₋ exceeding -12V to +12V may damage device. These limits apply with V+ = V- = 0.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS—Dual Supplies

(V+ = +4.5V to +5.5V, V- = -4.5V to -5.5V, V_{IH} = +2.4V, V_{IL} = +0.8V, GND = 0, T_A = T_{MIN} to T_{MAX}, unless otherwise noted. Typical values are at T_A = +25°C.) (Note 3)

Detailed Description

The MAX4711/MAX4712/MAX4713 differ considerably from traditional fault-protection switches, with several advantages. First, they are constructed with two parallel FET's allowing very low on-resistance. Second, they allow signals on the NC_ or NO_ pins that are within or slightly beyond the supply rails to be passed through the switch to the COM terminal, allowing rail-to-rail signal operation. Third, when a signal on NC_ or NO_ exceeds the supply rails by about 150mV (a fault condition) the voltage on COM_ is limited to the same polarity supply voltage. Operation is identical for both fault polarities.

During a fault condition, the NO_ or NC_ input becomes high impedance regardless of the switch state or load resistance. If the switch is on, the COM_ output current is supplied from V+ or V- by the clamp FET's that are connected from COM to each supply. These FET's can typically source or sink up to 15mA. When power is removed, the fault protection is still in effect. In this case, the NO_ or NC_ terminals are a virtual open circuit. The fault can be up to $\pm 12V$.

The COM_ pins are not fault-protected, they act as normal CMOS switch terminals. If a voltage source is connected to any COM_ pin, it should be limited to the supply voltages. Exceeding the supply voltage will

cause high currents to flow through the ESD-protected diodes, possibly damaging the device (see *Absolute Maximum Ratings*).

Pin Compatibility

These switches have identical pinouts to common non-fault-protected CMOS switches. Care should be exercised while considering them for direct replacements in existing printed circuit boards since only the NO_ and NC_ pins of each switch are fault-protected.

Internal Construction

Internal construction is shown in Figure 1, with the analog signal paths shown in bold. A single NO switch is shown; the NC configuration is identical except the logic-level translator is inverting. The analog switch is formed by the parallel combination of N-channel FET (N1) and P-channel FET (P1), which are driven on and off simultaneously according to the input fault condition and the logic-level state.

Normal Operation

Two comparators continuously compare the voltage on the NO_ (or NC_) pin with V+ and V-. When the signal on NO_ or NC_ is between V+ and V- the switch acts normally, with FETs N1 and P1 turning on and off in response to IN_ signals. The parallel combination of N1 and P1 forms a low-value resistor between NO_ (or

Fault-Protected, Low-Voltage, Quad SPST Analog Switches

MAX4711/MAX4712/MAX4713

Figure 1. Block Diagram

NC_) and COM_ so that signals pass equally well in either direction.

Positive Fault Condition

When the signal on NO_ (or NC_) exceeds V+ by about 150mV, the high-fault comparator output is high, turning off FETs N1 and P1. This makes the NO_ (or NC_) input high impedance regardless of the switch state. If the switch state is "off", all FETs are turned off and both NO_ (or NC_) and COM_ are high impedance. If the switch state is "on", clamp FET P2 is turned on, sourcing current from V+ to COM_.

Negative Fault Condition

When the signal on NO_ (or NC_) exceeds V- by about 150mV, the low-fault comparator output is high, turning off FETs N1 and P1. This makes the NO_ (or NC_) input high impedance regardless of the switch state. If the switch state is "off", all FETs are turned off and both NO_ (or NC_) and COM_ are high impedance. If the switch state is "on", clamp FET N2 is turned on, sinking current from COM_ to V-.

Transient Fault Response and Recovery

When a fast rise-time or fall-time transient on NC_ or NO_ exceeds V+ or V-, the output (COM_) follows the input to the supply rail with only a few nanoseconds delay. This delay is due to the switch on-resistance and circuit capacitance to ground. When the input transient returns to within the supply rails, however, there is a 700ns output recovery delay time. These values depend on the COM_ output resistance and capacitance, and are not production tested or guaranteed. The delays are not dependent on the fault amplitude. Higher COM_ output resistance and capacitance increase recovery times.

COM_ and IN_ Pins

FETs N2 and P2 can source about $\pm 15\text{mA}$ from V+ or V- to COM_ in the fault condition. Ensure that if the COM_ pin is connected to a low-resistance load, the absolute maximum current rating of 40mA is never exceeded both in normal and fault conditions.

Fault-Protected, Low-Voltage, Quad SPST Analog Switches

The COM_ pins do not have fault protection. Reverse ESD-protection diodes are internally connected between COM_ and V+ and V-. If a signal on COM_ exceeds V+ or V- by more than a diode drop, one of these diodes will conduct. The IN_ pin can exceed the positive supply voltage, but they can go below the negative supply by only a diode drop. The maximum voltage on these pins is 12V if operating from a single supply, regardless of the supply voltage (including 0 volts), and if operating from dual supplies, the maximum voltage is (V- + 12V).

Fault-Protection Voltage and Power Off

The maximum fault voltage on the NC_ or NO_ pins is ±12V with power off.

IN_ Logic-Level Thresholds

The logic-level thresholds are CMOS and TTL compatible when using ±4.5V to ±5.5V or single +4.5V to +11V supplies. When using a +2.7V supply, the logic thresholds are $V_{IH} = 2.0V$ and $V_{IL} = 0.6V$.

Dual Supplies

The MAX4711/MAX4712/MAX4713 operate with bipolar supplies between ±2.7V and ±5.5V. The V+ and V- supplies need not be symmetrical, but their difference should not exceed 11V.

Single Supply

The MAX4711/MAX4712/MAX4713 operate from a single supply between +2.7V and +11V when V- is connected to GND.
