Detailed Description

The MAX1749 is a low-quiescent-current, vibrator motor driver designed for battery-powered wireless handsets and pagers. The device supplies an adjustable +1.25V to +6.5V output for load currents up to 120mA. The MAX1749 allows for a constant vibration force while operating from a +2.5V to +6.5V input voltage range.

The 1.25V bandgap reference is connected to the error amplifier's inverting input. The error amplifier compares this reference with the feedback voltage and amplifies the difference. The MOSFET driver reads the error signal and applies the appropriate drive to the p-channel pass transistor. If the feedback voltage is lower than the reference voltage, the pass-transistor gate is pulled lower than the

reference, allowing more current to flow and increasing the output voltage. If the feedback voltage is too high, the pass-transistor gate is pulled-up, allowing less current to flow to the output. The output voltage is fed back to SET either directly for a 1.25V fixed output or through an external resistor-divider for an adjustable +1.25V to V_{IN} output. Additional blocks include a current limiter, reverse battery protection, a thermal sensor, and ON/OFF logic.

Internal P-Channel Pass Transistor

The MAX1749 features a 1.1 Ω typical P-channel MOSFET pass transistor. This provides several advantages over similar designs using PNP pass transistors, including longer battery life.

Figure 1. Functional Diagram

Figure 2. Adjustable Output Using External Feedback Resistors

The P-channel MOSFET requires no base drive current, which reduces quiescent current considerably. PNP-based regulators waste considerable amounts of base current under large loads. The MAX1749 does not suffer from these problems and consumes only 80µA of quiescent current independent of the load (see *Typical Operating Characteristics*).

Output Voltage Selection

To select the preset 1.25V output, connect OUT directly to SET. To adjust the output (1.25V to 6.5V), use two external resistors connected as a voltage divider to SET (Figure 2). The output voltage is set by the following equation:

$$V_{OUT} = V_{SET} (1 + R1 / R2)$$

where $V_{SET} = 1.25V$. To simplify resistor selection:

$$R1 = R2 \left(\frac{V_{OUT}}{V_{SET}} - 1 \right)$$

Choose $R2 = 100k\Omega$ to optimize power consumption, accuracy, and high-frequency power-supply rejection. The total current through the external resistive feedback and load should not be less than 10µA.

ON/OFF

Drive ON high to provide power to the load. Drive ON low to disable power to the load and reduce the supply current to typically 0.1nA (1µA max). Refer to the ON/OFF waveforms in the *Typical Operating Characteristics*. When ON goes high, output current rises to the current limit until V_{OUT} reaches regulation. While in regulation, the output current drops to a lower value sufficient to maintain motor speed. When ON goes low,

the regulator turns off; however, inertial energy in the motor exhibits a slow output voltage decline. The MAX1749 is designed to withstand this condition with no negative effects.

Current Limit

The MAX1749 includes a current limiter that monitors and controls the pass transistor's gate voltage, estimating the output current and limiting it to about 280mA. For design purposes, the current limit should be considered 120mA (min) to 420mA (max). The output can be shorted to ground for an infinite time period without damaging the part.

Thermal-Overload Protection

Thermal-overload protection limits total power dissipation in the MAX1749. When the junction temperature exceeds $T_J = +170^\circ C$, the thermal sensor sends a signal to the ON/OFF logic, turning off the pass transistor and allowing the IC to cool. The thermal sensor will turn the pass transistor on again after the IC's junction temperature cools by typically 20°C, resulting in a pulsed output during continuous thermal-overload conditions.

Operating Region and Power Dissipation

Maximum power dissipation of the MAX1749 depends on the thermal resistance of the case and circuit board, the temperature difference between the die junction and ambient air, and the rate of air flow. The power dissipation across the device is $P = I_{OUT} (V_{IN} - V_{OUT})$. The resulting maximum power dissipation is:

$$P_{MAX} = (T_J - T_A) / \theta_{JA}$$

where $(T_J - T_A)$ is the temperature difference between the MAX1749 die junction and the surrounding air, and θ_{JA} is +140°C/W.

GND performs the dual function of providing an electrical connection to ground and channeling heat away. Connect GND to a large pad or ground plane.

Reverse Battery Protection

The MAX1749 has a unique protection scheme that limits the reverse supply current to less than 1mA when either V_{IN} or V_{ON} falls below ground. The circuitry monitors the polarity of these two pins, disconnecting the internal circuitry and parasitic diodes when the battery is reversed. This feature prevents the device from overheating and damaging the battery.

$V_{IN} > 5.5V$ Minimum Load Current

When operating the MAX1749 with an input voltage above 5.5V, the minimum current through the external feedback resistors and load must be 30µA.

Capacitor Selection and Regulator Stability

Use a 1 μ F capacitor on the input and a 1 μ F capacitor on the output of the MAX1749. A higher-value input capacitor (10 μ F) may be necessary if large, fast transients are anticipated and the device is located several inches from the power source. Improve load-transient response and stability by using larger output capacitors. For stable operation over the full temperature range with load currents up to 120mA, use a 1 μ F min capacitor (ESR < 0.2 Ω).
