

## Ordering Information

Part Number	Temperature Range	Package
MICRF213AYQS	-40°C to +105°C	16-Pin QSOP

## Pin Configuration

**16-Pin QSOP (QS)  
(Top View)**

## Pin Description

16-Pin QSOP	Pin Name	Pin Function
1	RO1	Reference resonator input connection to Colpitts oscillator stage. May also be driven by external reference signal of 1.5V p-p amplitude maximum.
2	GNDRF	Negative supply connection associated with ANT RF input.
3	ANT	RF signal input from antenna. Internally AC-coupled. It is recommended that a matching network with an inductor-to-RF ground is used to improve ESD protection.
4	GNDRF	Negative supply connection associated with ANT RF input.
5	VDD	Positive supply connection for all chip functions.
6	SQ	Squelch control logic input with an active internal pull-up when not shut down.
7	SEL0	Logic control input with active internal pull-up. Used in conjunction with SEL1 to control the demodulator low pass filter bandwidth. (See filter table for SEL0 and SEL1 in application section)
8	SHDN	Shutdown logic control input. Active internal pull-up.
9	GND	Negative supply connection for all chip functions except RF input.
10	DO	Demodulated data output.
11	SEL1	Logic control input with active internal pull-up. Used in conjunction with SEL0 to control the demodulator low pass filter bandwidth. (See filter table for SEL0 and SEL1 in application subsection)
12	CTH	Demodulation threshold voltage integration capacitor connection. Tie an external capacitor across CTH pin and GND to set the settling time for the demodulation data slicing level. Values above 1nF are recommended and should be optimized for data rate and data profile.
13	CAGC	AGC filter capacitor connection. CAGC capacitor, normally greater than 0.47uF, is connected from this pin to GND
14	RSSI	Received signal strength indication output. Output is from a buffer with 200 ohms typical output impedance.
15	NC	Not Connected (Connect to Ground)
16	RO2	Reference resonator input connection to Colpitts oscillator stage, 7pF, in parallel with low resistance MOS switch-to-GND, during normal operation. Driven by startup excitation circuit during the internal startup control sequence.

### Absolute Maximum Ratings<sup>(1)</sup>

Supply Voltage (V<sub>DD</sub>) .....+5V  
 Input Voltage .....+5V  
 Junction Temperature ..... +150°C  
 Lead Temperature (soldering, 10sec.) ..... 260°C  
 Storage Temperature (T<sub>S</sub>).....-65°C to +150°C  
 Maximum Receiver Input Power .....+10dBm  
 ESD Rating<sup>(3)</sup> ..... 3KV HBM

### Operating Ratings<sup>(2)</sup>

Supply voltage (V<sub>DD</sub>) .....+3.0V to +3.6V  
 Ambient Temperature (T<sub>A</sub>) ..... -40°C to +105°C  
 Input Voltage (V<sub>IN</sub>) ..... 3.6V (Max)  
 Maximum Input RF Power ..... -20dBm

### Electrical Characteristics<sup>(4)</sup>

Specifications apply for 3.0V < V<sub>DD</sub> < 3.6V, V<sub>SS</sub> = 0V, C<sub>AGC</sub> = 4.7µF, C<sub>TH</sub> = 0.47µF, f<sub>RX</sub> = 315MHz unless otherwise noted.  
**Bold** values indicate -40°C - T<sub>A</sub> - +105°C. 900bps data rate (Manchester encoded), reference oscillator frequency = 9.81563MHz.

Symbol	Parameter	Condition	Min	Typ	Max	Units
I <sub>DD</sub>	Operating Supply Current	Continuous Operation, f <sub>RX</sub> = 315MHz		3.9		mA
I <sub>SHUT</sub>	Shut down Current			0.33		µA
<b>RF/IF Section</b>						
	Image Rejection			20		dB
	1 <sup>st</sup> IF Center Frequency	f <sub>RX</sub> = 315MHz		0.86		MHz
	Receiver Sensitivity @ 1kbps	f <sub>RX</sub> = 315MHz (matched to 50Ω) BER=10 <sup>-2</sup>		-110		dBm
	IF Bandwidth	f <sub>RX</sub> = 315MHz		235		kHz
	Antenna Input Impedance	f <sub>RX</sub> = 315MHz		32.5 – j235		Ω
	Receive Modulation Duty Cycle	<b>Note 5</b>	20		80	%
	AGC Attack / Decay Ratio	t <sub>ATTACK</sub> / t <sub>DECAY</sub>		0.1		
	AGC pin leakage current	T <sub>A</sub> = 25°C T <sub>A</sub> = +105°C		±2 ±800		nA nA
	AGC Dynamic Range	RF <sub>IN</sub> @ -50dBm		1.13		V
		RF <sub>IN</sub> @ -110dBm		1.70		V

	Reference Oscillator Frequency	f <sub>RX</sub> = 315MHz Crystal Load Cap = 10pF		9.81563		MHz
	Reference Oscillator Input Impedance			300		kΩ
	Reference Oscillator Input Range		0.2		1.5	Vp-p
	Reference Oscillator Source Current	V(REFOSC) = 0V		3.5		µA

**Notes:**

- Exceeding the absolute maximum rating may damage the device.
- The device is not guaranteed to function outside of its operating rating.
- Device is ESD sensitive. Use appropriate ESD precautions. Exceeding the absolute maximum rating may damage the device.
- Sensitivity is defined as the average signal level measured at the input necessary to achieve 10<sup>-2</sup> BER (bit error rate). The input signal is defined as a return-to-zero (RZ) waveform with 50% average duty cycle (Manchester encoded) at a data rate of 1kbps.
- When data burst does not contain preamble, duty cycle is defined as total duty cycle, including any “quiet” time between data bursts. When data bursts contain preamble sufficient to charge the slice level on capacitor C<sub>TH</sub>, then duty cycle is the effective duty cycle of the burst alone. [For example, 100msec burst with 50% duty cycle, and 100msec “quiet” time between bursts. If burst includes preamble, duty cycle is Ton/(Ton+Toff) = 50%; without preamble, duty cycle is Ton/(Ton+ Toff + Tquiet) = 50msec/(200msec)=25%. Ton is the (Average number of 1's/burst) x bit time, and Toff = Tburst -Ton.)

## Electrical Characteristics<sup>(4)</sup>

Specifications apply for  $3.0V < V_{DD} < 3.6V$ ,  $V_{SS} = 0V$ ,  $C_{AGC} = 4.7\mu F$ ,  $C_{TH} = 0.47\mu F$ ,  $f_{RX} = 315MHz$  unless otherwise noted.

**Bold** values indicate  $-40^{\circ}C - T_A - +105^{\circ}C$ . 900bps data rate (Manchester encoded), reference oscillator frequency = 9.81563MHz.

Symbol	Parameter	Condition	Min	Typ	Max	Units
<b>Demodulator</b>						
	CTH Source Impedance	$F_{REFOSC} = 9.81563MHz$		165		k $\Omega$
	CTH Leakage Current	$T_A = 25^{\circ}C$ $T_A = +105^{\circ}C$		$\pm 2$ $\pm 800$		nA nA

## Sensitivity Graphs

## Functional Diagram

Figure 1. Simplified Block Diagram

## Functional Description

Figure 1 shows the basic structure of the MICRF213. It is made of three sub-blocks: Image Rejection UHF Down-converter, the OOK Demodulator, and Reference and Control Logics. Outside the device, the MICRF213 requires only three components to operate; two capacitors (CTH, and CAGC) and the reference frequency device, usually a quartz crystal. An additional five components may be used to improve performance. These are: power supply decoupling capacitor, two components for the matching network and two components for the pre-selector band pass filter.

## Receiver Operation

### LNA

The RF input signal is AC-coupled into the gate circuit of the grounded source LNA input stage. The LNA is a Cascoded NMOS.

### Mixers and Synthesizer

The LO ports of the Mixers are driven by quadrature local oscillator outputs from the synthesizer block. The local oscillator signal from the synthesizer is placed on the low side of the desired RF signal. This allows suppression of the image frequency at twice the IF frequency below the wanted signal. The local oscillator

is set to 32 times the crystal reference frequency via a phase-locked loop synthesizer with a fully integrated loop filter.

### Image Reject Filter and Band-Pass Filter

The IF ports of the mixer produce quadrature down converted IF signals. These IF signals are low-pass filtered. This removes higher frequency products prior to the image reject filter where they are combined to reject the image frequencies. The IF signal then passes through a third order band pass filter. The IF center frequency is 0.86MHz. The IF BW is 235KHz @ 315MHz, this will vary with RF operating frequency. The IF BW can be calculated via direct scaling:

$$BW_{IF} = BW_{IF@315MHz} \times \left( \frac{\text{Operating Freq (MHz)}}{315} \right)$$

These filters are fully integrated inside the MICRF213.

After filtering, four active gain controlled amplifier stages enhance the IF signal to proper level for demodulation.

### OOK Demodulator

The demodulator section is comprised of detector, programmable low pass filter, slicer, and AGC comparator.

**Detector and Programmable Low-Pass Filter**

The demodulation starts with the detector removing the carrier from the IF signal. Post detection, the signal becomes base band information. The programmable low-pass filter further enhances the base band information. There are four programmable low-pass filter BW settings: 1180Hz, 2360Hz, 4270Hz, 9400Hz for 315MHz operation. Low pass filter BW will vary with RF Operating Frequency. Filter BW values can be easily calculated by direct scaling. See the equation below for the filter BW calculation:

$$BW_{\text{Operating Freq}} = BW_{\text{@315MHz}} \times \left( \frac{\text{Operating Freq (MHz)}}{315} \right)$$

It is very important to choose filter setting that best fits the intended data rate as this will minimize data distortion.

Demod BW is set at 9700Hz @ 315MHz as default (assuming both SEL0 and SEL1 pins are floating). The low pass filter can be hardware set by external pins SEL0 and SEL1.

SEL0	SEL1	Demod BW (@ 315MHz)
0	0	1180Hz
1	0	2360Hz
0	1	4270Hz
1	1	9400Hz - default

Table 1. Demodulation BW Selection

**Slicer, Slicing Level and Squelch**

The signal, prior to slicer, is still linear demodulated AM. Data slicer converts this signal into digital “1”s and “0”s by comparing with the threshold voltage built up on the CTH capacitor. This threshold is determined by detecting the positive and negative peaks of the data signal and storing the mean value. Slicing threshold default is 50%. After the slicer, the signal becomes digital OOK data.

During long periods of “0”s or no data period at all, threshold voltage on the CTH capacitor may be very low. Large random noise spikes during this time may cause erroneous “1”s at DO pin. Squelch pin when pull down low will suppress these errors.

**AGC Comparator**

The AGC comparator monitors the signal amplitude from the output of the programmable low-pass filter. When the output signal is less than 750mV threshold,

1.5µA current is then sourced into the external CAGC capacitor. When the output signal is greater than 750mV, a 15µA current sink discharges the CAGC capacitor. The voltage, developed on the CAGC capacitor, acts to adjust the gain of the mixer and the IF amplifier to compensate for RF input signal level variation.

**Reference Control**

There are two components in the Reference Control sub-block: 1) Reference Oscillator and, 2) Control Logic through parallel Inputs: SEL0, SEL1, SHDN.

**Reference Oscillator**

Figure 2. Reference Oscillator Circuit

The reference oscillator in the MICRF213 (reference Figure 2) uses a basic Colpitts crystal oscillator configuration with a MOS transistor to provide negative resistance. All capacitors shown in the figure are integrated inside MICRF213. R01 and R02 are external pins of MICRF213. The user only need connect the reference oscillation crystal.

Reference oscillator crystal frequency can be calculated thus as:

$$F_{\text{REFOSC}} = F_{\text{RF}} / (32 + 1.1/12)$$

For 315MHz,  $F_{\text{REFOSC}} = 9.81563 \text{ MHz}$ .

To operate the MICRF213 with minimum offset, crystal frequencies should be specified with 10pF loading capacitance.

## Application Information

Figure 3. QR213HE1 Application Example, 315MHz

The MICRF213 can be fully tested by using one of the many evaluation boards designed by Micrel and intended for use with this device. As an entry level, the QR213HE1 (reference Figure 3) offers a good start for most applications. It has a helical PCB antenna with its matching network, a band-pass-filter front-end as a pre-selector filter, matching network and the minimum components required to make the device work. The minimum components are a crystal, Cagc, and Cth capacitors. By removing the matching network of the helical PCB antenna (C9 and L3), a whip antenna (ANT2) or a RF connector (J2) can be used instead. Figure 3 shows the entire schematic for 315MHz. Other frequencies can be used and the values needed are listed in the tables below.

Capacitor C9 and inductor L3 are the passive elements for the helical PCB matching network. It is recommended that a tight tolerance be used for these devices; such as 2% for the inductor and 0.1pF for the capacitor. PCB variations may require different values and optimization. Table 2 shows the matching elements for the device frequency range. For additional information, reference the: Small PCB Antennas for Micrel RF Products application note.

Freq (MHz)	C9 (pF)	L3 (nH)
303.825	1.2	82
315	1.2	75
345	1.2	62

Table 2. Matching Values for the Helical PCB Antenna

To use another antenna, such as the whip kind, remove

C9 and place the whip antenna in the hole provided in the PCB. Also, a RF signal can be injected there.

L1 and C8 form the pass-band-filter front-end. Its purpose is to attenuate undesired outside band noise which reduces the receiver performance. It is calculated by the parallel resonance equation  $f = 1/(2*PI*(SQRT(L1*C8)))$ . Table 3 shows the most used frequency values.

Freq (MHz)	C8 (pF)	L1 (nH)
303.825	6.8	39
315	6.8	39
345	5.6	39

Table 3. Band-Pass-Filter Front-End Values

There is no need for the band-pass-filter front-end for applications where it is proven the outside band noise does not cause a problem. The MICRF213 has image reject mixers which improve significantly the selectivity and rejection of outside band noise.

Capacitor C3 and inductor L2 form the L-shape matching network. The capacitor provides additional attenuation for low frequency outside band noise and the inductor provides additional ESD protection for the antenna pin. Two ways can be used to find these values, which are matched close to 50Ω. One method is done by calculating the values using the equations below and another by using a Smith chart. The latter is made easier by using software that plots the values of the components C8 and L1, like WinSmith by Noble Publishing.

To calculate the matching values, one needs to know

the input impedance of the device. Table 4 shows the input impedance of the MICRF213 and the suggested matching values used for the most frequencies. Please keep in mind that these suggested values may be different if the layout is not exactly the same as the one depicted here.

Freq (MHz)	C3 (pF)	L2 (nH)	Z device (Ω)
303.825	1.8	72	34.6 – j245.1
315	1.8	68	32.5 – j235
345	1.8	56	25.3 – j214

**Table 4. Matching Values for the Most Used Frequencies**

For the frequency of 315MHz, the input impedance is  $Z = 32.5 - j235\Omega$ , then the matching components are calculated by:

Equivalent parallel =  $B = 1/Z = 0.577 + j4.175$  msiemens

$R_p = 1 / \text{Re} (B)$ ;  $X_p = 1 / \text{Im} (B)$

$R_p = 1.733 \text{ k}\Omega$ ;  $X_p = 239.5 \Omega$

$Q = \text{SQRT} (R_p/50 + 1)$

$Q = 5.972$

$X_m = R_p / Q$

$X_m = 290.21 \Omega$

Resonance Method For L-shape Matching Network

$L_c = X_p / (2.Pi.f)$ ;  $L_p = X_m / (2.Pi.f)$

$L_2 = (L_c.L_p) / (L_c + L_p)$ ;  $C_3 = 1 / (2.Pi.f.X_m)$

$L_2 = 66.3\text{nH}$

$C_3 = 1.74\text{pF}$

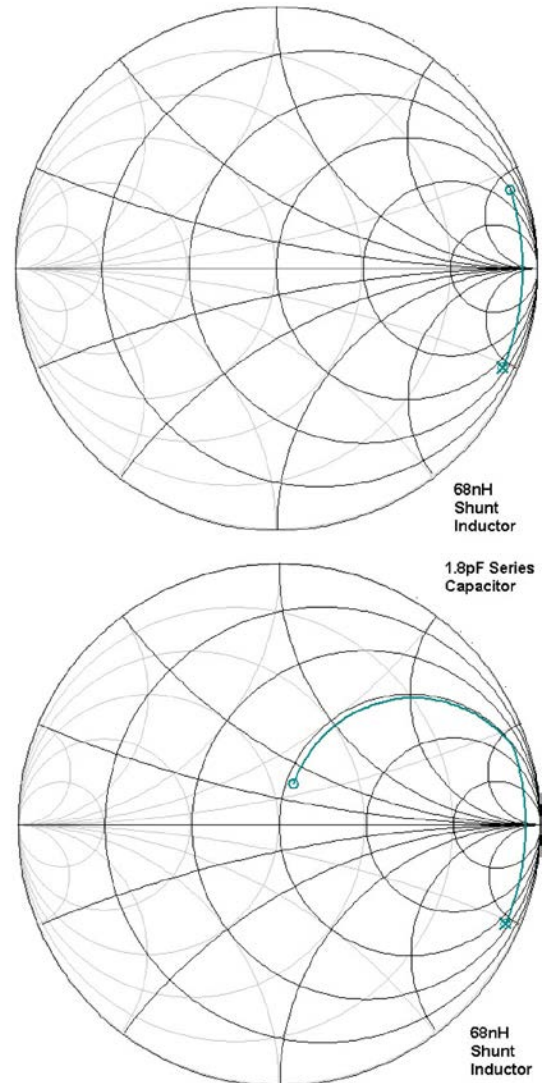

Doing the same calculation example with the Smith Chart, it would appear as follows,

First, we plot the input impedance of the device, ( $Z = 32.5 - j235\Omega$  @ 315MHz.(Figure 4).

**Figure 4. Device’s Input Impedance,  $Z = 32.5 - j235 \Omega$**

Second, we plot the shunt inductor (68nH) and the series capacitor (1.8pF) for the desired input impedance (Figure 5). We can see the matching leading to the center of the Smith Chart or close to 50Ω.

**Figure 5. Plotting the Shunt Inductor and Series Capacitor**

Crystal Y1 or Y1A (SMT or leaded respectively) is the reference clock for all the device internal circuits. Desired crystal characteristics are: 10pF load capacitance, 30ppm, ESR < 50Ω and a -40°C to +105°C temperature range. Table 5 shows the crystal frequencies and one of Micrel’s approved crystal manufactures ([www.hib.com.br](http://www.hib.com.br)).

The oscillator of the MICRF213 is a Colpitts type. It is very sensitive to stray capacitance loads. Thus, very good care must be taken when laying out the printed circuit board. Avoid long traces and ground plane on

the top layer close to the REFOSC pins RO1 and RO2. When care is not taken in the layout, and crystals from other vendors are used, the oscillator may take longer times to start as well as the time to good data in the DO pin to show up. In some cases, if the stray capacitance is too high (>20pF), the oscillator may not start at all.

The crystal frequency is calculated by  $REFOSC = RF \text{ Carrier} / (32 + (1.1/12))$ . The local oscillator is low side injection ( $32 \times 9.81563\text{MHz} = 314.1\text{MHz}$ ), that is, its frequency is below the RF carrier frequency and the image frequency is below the LO frequency. Refer to Figure 6. The product of the incoming RF signal and local oscillator signal will yield the IF frequency, which will then be demodulated by the detector of the device.

Figure 6. Low Side Injection Local Oscillator

REFOSC (MHz)	Carrier (MHz)	HIB Part Number
9.467411	303.825	SA-9.467411-F-10-H-30-30-X
9.81563	315	SA-9.815630-F-10-H-30-30-X
10.75045	345.0	SA-10.750450-F-10-H-30-30-X

Table 5. Crystal Frequency and Vendor Part Number

JP1 and JP2 are the bandwidth selection for the demodulator bandwidth. To set it correctly, it is necessary to know the shortest pulse width of the encoded data sent in the transmitter. Reference the example of the data profile, in the Figure 7, below:

Figure 7. Example of a Data Profile

PW2 is shorter than PW1, so PW2 should be used for the demodulator bandwidth calculation. The calculation is found by  $0.65/\text{shortest pulse width}$ . After this value is found, the setting should be done

according to Table 6. For example, if the pulse period is  $140\mu\text{sec}$ , 50% duty cycle, then the pulse width will be  $70\mu\text{sec}$  ( $PW = (140 \mu\text{sec} * 50\%) / 100$ ). So, a bandwidth of  $9.286\text{kHz}$  would be necessary ( $0.65 / 70\mu\text{sec}$ ). However, if this data stream had a pulse period with a 20% duty cycle, then the bandwidth required would be  $23.2\text{kHz}$  ( $0.65 / 28\mu\text{sec}$ ), which exceeds the maximum bandwidth of the demodulator circuit. If one tries to exceed the maximum bandwidth, the pulse would appear stretched or wider.

SEL0 JP1	SEL1 JP2	Demod. BW (hertz)	Shortest Pulse (usec)	Maximum baud rate for 50% Duty Cycle (hertz)
Short	Short	1180	551	908
Open	Short	2360	275	1815
Short	Open	4720	138	3631
Open	Open	9400	69	7230

Table 6. JP1 and JP2 Setting, 315MHz

Capacitors C6 and C4, Cth and Cagc capacitors respectively, provide the time base reference for the data pattern received. These capacitors are selected according to data profile, pulse duty cycle, dead time between two received data packets and if the data pattern has or not a preamble. See Figure 7 for an example of a data profile.

Other frequencies will have different demodulator bandwidth limits, which are derived from the reference oscillator frequency. Table 7 and Table 8, below, show the limits for the other two most used frequencies.

SEL0 JP1	SEL1 JP2	Demod. BW (hertz)	Shortest Pulse (usec)	Maximum baud rate for 50% Duty Cycle (hertz)
Short	Short	1140	570	8770
Open	Short	2280	285	1754

Open	Short	2800	47nF	2.2uF
Short	Open	5300	22nF	1uF
Open	Open	9700	10nF	0.47uF

**Table 9. Suggested Cth and Cagc Values**

JP3 is a jumper used to configure the digital squelch function. When it is high, there is no squelch applied to the digital circuits and the DO (data out) pin yields a hash signal. When the pin is low, the DO pin activity is considerably reduced. It will have more or less than shown in the figure below depending upon the outside band noise. The penalty for using squelch is a delay in obtaining a good signal in the DO pin. That is, it takes longer for the data to show up. The delay is dependent upon many factors such as RF signal intensity, data profile, data rate, Cth and Cagc capacitor values, and outside band noise. See Figure 8 and 9.

**Figure 8. Data Out Pin with No Squelch (SQ = 1)**

**Figure 9. Data Out Pin with Squelch (SQ = 0)**

Other components used include: C5, which is a decoupling capacitor for the Vdd line; R4 reserved for future use and not needed for the evaluation board; R3 for the shutdown pin (SHDN = 0, device is operation), which can be removed if that pin is connected to a microcontroller or an external switch; and R1 and R2 which form a voltage divider for the AGC pin. One can force a voltage in this AGC pin to purposely decrease the device sensitivity. Special care is needed when doing this operation, as an external control of the AGC voltage may vary from lot to lot and may not work the same in several devices.

Three other pins need to be discussed as well. They are the DO, RSSI, and shut down pins. The DO pin has a driving capability of 0.4mA. This is good enough for most of the logic families ICs in the market today. The RSSI pin provides a transfer function of the RF signal intensity vs. voltage. It is very useful to determine the signal to noise ratio of the RF link, crude range estimate from the transmitter source and AM demodulation, which requires a low Cagc capacitor value.

The shut down pin (SHDN) is useful to save energy. Making its level close to Vdd (SHDN = 1), the device is then not in operation. Its DC current consumption is less than 1µA (do not forget to remove R3). When toggling from high to low, there will be a time required for the device to come to steady state mode, and a time for data to show up in the DO pin. This time will be dependent upon many things such as temperature, crystal used, and if there is an external oscillator with faster startup time. Crystal vendors suggest that the data will show up in the DO pin around 1msec time, and 2msec over the temperature range of the device. See Figure 10.

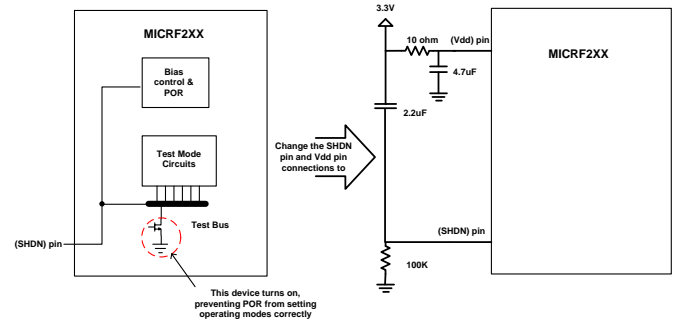

**Figure 10. Time-to-Good Data After Shut Down Cycle, Room Temperature**

**Important Note**

A few customers have reported that some MICRF213 receivers do not start up correctly. When the issue occurs, DO either chatters or stays at low voltage level. An unusual operating current is observed and the part cannot receive or demodulate data even when a strong OOK signal is present.

Micrel has confirmed that this is the symptom of incorrect power on reset (POR) of internal register bits. The MICRF213 is designed to start up in shutdown mode (SHDN pin must be in logic high during Vdd ramp up). When the SHDN pin is tied to GND, and if the supply is ramped up slowly, a “test bus pull down” circuit may be activated. Once the chip enters this mode, the POR does not have the chance to set register bits (and hence operating modes) correctly. The test bus pull down acts on the SHDN pin, and can be illustrated as the following diagram.

To prevent the erroneous startup, a simple RC network is recommended. The 10Ω resistor and the 4.7μF capacitor provide a delay of about 200μs between the VDD and SHDN during the power up, thus ensuring the part to enter to shutdown stage before the part is actually turned on. The 2.2μF capacitor bootstraps the voltage on SHDN, ensuring that SHDN voltage leads the supply voltage on Vdd during the power up. This gives the POR circuit time to set internal register bits. The SHDN pin can be brought low to turn the chip on once the initialization is completed. The 2.2μF and 100kΩ network form a RC delay of about 200ms before the SHDN pin is brought to low again. The 100kΩ resistor discharges the SHDN pin to turn the chip on.

The suggestion provided above will generally serve to prevent the startup issue from happening to the MICRF213 series ASK receiver. However, exact values of the RC network depend on the ramp rate of the supply voltage, and should be determined on a case-by-case basis.

**PCB Considerations and Layout**

Figures 11 to 16 show some of the printed circuit layers for the QR211HE1 board. The MICRF213 shares the exact same board with different component values. Use the Gerber files provided (downloadable from Micrel Website: [www.micrel.com](http://www.micrel.com)) which have the remaining layers needed to fabricate this board. When copying or making one's own boards, be sure and make the traces as short as possible. Long traces alter the matching network and the values suggested are no longer valid. Suggested Matching Values may vary due to PCB variations. A PCB trace 100 mills (2.5mm) long has about 1.1nH of inductance. Optimization should always be done with exhaustive range tests. Make individual ground connections to the ground plane with a via for each ground

connection. Do not share vias with ground connections. Each ground connection = 1 via or more vias. Ground plane must be solid and possibly without interruptions. Avoid ground plane on top next to the matching elements. It normally adds additional stray capacitance which changes the matching. Do not use phenolic material, only FR4 or better materials. Phenolic material is conductive above 200MHz. The RF path should be as straight as possible avoiding loops and unnecessary turns. Separate ground and Vdd lines from other circuits (microcontroller, etc). Known sources of noise should be laid out as far as possible from the RF circuits. Avoid thick traces, the higher the frequency, the thinner the trace should be in order to minimize losses in the RF path.

Micrel, Inc. is a leading global manufacturer of IC solutions for the worldwide high performance linear and power, LAN, and timing & communications markets. The Company's products include advanced mixed-signal, analog & power semiconductors; high-performance communication, clock management, MEMs-based clock oscillators & crystal-less clock generators, Ethernet switches, and physical layer transceiver ICs. Company customers include leading manufacturers of enterprise, consumer, industrial, mobile, telecommunications, automotive, and computer products. Corporation headquarters and state-of-the-art wafer fabrication facilities are located in San Jose, CA, with regional sales and support offices and advanced technology design centers situated throughout the Americas, Europe, and Asia. Additionally, the Company maintains an extensive network of distributors and reps worldwide.

Micrel makes no representations or warranties with respect to the accuracy or completeness of the information furnished in this datasheet. This information is not intended as a warranty and Micrel does not assume responsibility for its use. Micrel reserves the right to change circuitry, specifications and descriptions at any time without notice. No license, whether express, implied, arising by estoppel or otherwise, to any intellectual property rights is granted by this document. Except as provided in Micrel's terms and conditions of sale for such products, Micrel assumes no liability whatsoever, and Micrel disclaims any express or implied warranty relating to the sale and/or use of Micrel products including liability or warranties relating to fitness for a particular purpose, merchantability, or infringement of any patent, copyright, or other intellectual property right.

Micrel Products are not designed or authorized for use as components in life support appliances, devices or systems where malfunction of a product can reasonably be expected to result in personal injury. Life support devices or systems are devices or systems that (a) are intended for surgical implant into the body or (b) support or sustain life, and whose failure to perform can be reasonably expected to result in a significant injury to the user. A Purchaser's use or sale of Micrel Products for use in life support appliances, devices or systems is a Purchaser's own risk and Purchaser agrees to fully indemnify Micrel for any damages resulting from such use or sale.
