1.0 Introduction

The Intel® Pentium® III processor for the PGA370 socket is the next member of the P6 family, in the Intel IA-32 processor line and hereafter will be referred to as the "Pentium III processor", or simply "the processor". The processor uses the same core and offers the same performance as the Pentium III processor for the SC242 connector, but utilizes a package technology called flip-chip pin grid array, or FC-PGA. This package utilizes the same 370-pin zero insertion force socket (PGA370) used by the Intel® Celeron™ processor. Thermal solutions are attached directly to the back of the processor core package without the use of a thermal plate or heat spreader. As core frequencies increase, the need for better power dissipation arises, so an Integrated Heat Spreader (IHS) has been introduced at the higher frequencies near 1B GHz. The package with an IHS is called FC-PGA2.

The Pentium III processor, like its predecessors in the P6 family of processors, implements a Dynamic Execution microarchitecture—a unique combination of multiple branch prediction, data flow analysis, and speculative execution. This enables these processors to deliver higher performance than the Pentium processor, while maintaining binary compatibility with all previous Intel Architecture processors. The processor also executes Intel® MMX™ technology instructions for enhanced media and communication performance just as it's predecessor, the Pentium III processor. Additionally, Pentium III processor executes Streaming SIMD (single-instruction, multiple data) Extensions for enhanced floating point and 3-D application performance. The concept of processor identification, via CPUID, is extended in the processor family with the addition of a processor serial number. Refer to the *Intel® Processor Serial Number* application note for more detailed information. The processor utilizes multiple low-power states such as AutoHALT, Stop-Grant, Sleep, and Deep Sleep to conserve power during idle times.

The processor includes an integrated on-die, 256-KB, 8-way set associative level-two (L2) cache. The L2 cache implements the new Advanced Transfer Cache Architecture with a 256-bit wide bus. The processor also includes a 16-KB level one (L1) instruction cache and 16-KB L1 data cache. These cache arrays run at the full speed of the processor core. As with the Pentium III processor for the SC242 connector, the Pentium III processor for the PGA370 socket has a dedicated L2 cache bus, thus maintaining the dual independent bus architecture to deliver high bus bandwidth and performance (see Figure 1). Memory is cacheable for 64 GB of addressable memory space, allowing significant headroom for desktop systems. Refer to the Specification Update document for this processor to determine the cacheability and cache configuration options for a specific processor. The Specification Update document can be requested at your nearest Intel sales office.

The processor utilizes the same multiprocessing system bus technology as the Pentium II processor. This allows for a higher level of performance for both uni-processor and two-way multiprocessor systems. The system bus uses a variant of GTL+ signaling technology called Assisted Gunning Transceiver Logic (AGTL+/AGTL) signaling technology.

1.1   Terminology

In this document, a '#' symbol after a signal name refers to an active low signal. This means that a signal is in the active state (based on the name of the signal) when driven to a low level. For example, when FLUSH# is low, a flush has been requested. When NMI is high, a nonmaskable interrupt has occurred. In the case of signals where the name does not imply an active state but describes part of a binary sequence (such as *address* or *data*), the '#' symbol implies that the signal is inverted. For example, D[3:0] = 'HLHL' refers to a hex 'A', and D[3:0]# = 'LHLH' also refers to a hex 'A' (H= High logic level, L= Low logic level).

The term "system bus" refers to the interface between the processor, system core logic (a.k.a. the chipset components), and other bus agents.

1.1.1   Package and Processor Terminology

The following terms are used often in this document and are explained here for clarification:

- **Pentium III processor** - The entire product including all internal components.

- **PGA370 socket** - 370-pin Zero Insertion Force (ZIF) socket which a FC-PGA or PPGA packaged processor plugs into.

- **FC-PGA** - Flip Chip Pin Grid Array. The package technology used on Pentium III processors for the PGA370 socket.

- **FC-PGA2** - Flip Chip Pin Grid Array with an Integrated Heat Spreader (IHS). The package technology used on Pentium III processors for the PGA370 socket for increased power dissipation away from the die. The IHS covers the die and has a very low thermal resistance.

- **Integrated Heat Spreader (IHS)** - The IHS is a metal cover on the die and is an integral part of the CPU. The IHS promotes heat spreading away from the die backside to ease thermal constraints.

- **Advanced Transfer Cache (ATC)** - New L2 cache architecture unique to the 0.18 micron Pentium III processors. ATC consists of microarchitectural improvements that provide a higher data bandwidth interface into the processor core that is completely scaleable with the processor core frequency.

- **Keep-out zone** - The area on or near a FC-PGA packaged processor that system designs can not utilize.

- **Keep-in zone** - The area of a FC-PGA packaged processor that thermal solutions may utilize.

- **OLGA** - Organic Land Grid Array. The package technology for the core used in S.E.C.C. 2 processors that permits attachment of the heatsink directly to the die.

- **PPGA - Plastic Pin Grid Array.** The package technology used for Celeron processors that utilize the PGA370 socket.

- **Processor** - For this document, the term processor is the generic form of the Pentium III processor for the PGA370 socket in the FC-PGA package.

- **Processor core** - The processor's execution engine.

- **S.E.C.C.** - The processor package technology called "Single Edge Contact Cartridge". Used with Intel® Pentium® II processors.

- **S.E.C.C. 2** - The follow-on to S.E.C.C. processor package technology. This differs from its predecessor in that it has no extended thermal plate, thus reducing thermal resistance. Used with Pentium III processors and latest versions of the Pentium II processor.

- **SC242** - The 242-contact slot connector (previously referred to as slot 1 connector) that the S.E.C.C. and S.E.C.C. 2 plug into, just as the Intel® Pentium® Pro processor uses socket 8.

The cache and L2 cache are an industry designated names.

1.1.2 Processor Naming Convention

A letter(s) is added to certain processors (e.g., 600EB MHz) when the core frequency alone may not uniquely identify the processor. Below is a summary of what each letter means as well as a table listing all the available Pentium III processors for the PGA370 socket.

"B" — 133 MHz System Bus Frequency

"E" — Processor with "Advanced Transfer Cache" (CPUID 068xh and greater)

Table 1. Processor Identification

Processor	Core Frequency (MHz)	System Bus Frequency (MHz)	L2 Cache Size (Kbytes)	L2 Cache Type[2]	CPUID[1]
500E	500	100	256	ATC	068xh
533EB	533	133	256	ATC	068xh
550E	550	100	256	ATC	068xh
600E	600	100	256	ATC	068xh
600EB	600	133	256	ATC	068xh
650	650	100	256	ATC	068xh
667	667	133	256	ATC	068xh
700	700	100	256	ATC	068xh
733	733	133	256	ATC	068xh
750	750	100	256	ATC	068xh
800	800	100	256	ATC	068xh
800EB	800	133	256	ATC	068xh
850	850	100	256	ATC	068xh
866	866	133	256	ATC	068xh
900	900	100	256	ATC	068xh
933	933	133	256	ATC	068xh
1 GHz	1000	100	256	ATC	068xh
1B GHz	1000	133	256	ATC	068xh
1.10 GHz	1100	100	256	ATC	068xh
1.13 GHz	1133	133	256	ATC	068xh

NOTES:
1. Refer to the *Pentium® III Processor Specification Update* for the exact CPUID for each processor.
2. ATC = Advanced Transfer Cache. ATC is an L2 Cache integrated on the same die as the processor core. With ATC, the interface between the processor core and L2 Cache is 256-bits wide, runs at the same frequency as the processor core and has enhanced buffering.

Datasheet

2.0 Electrical Specifications

2.1 Processor System Bus and V_{REF}

The Pentium III processor signals use a variation of the low voltage Gunning Transceiver Logic (GTL) signaling technology.

The Pentium Pro processor system bus specification is similar to the GTL specification, but was enhanced to provide larger noise margins and reduced ringing. The improvements are accomplished by increasing the termination voltage level and controlling the edge rates. This specification is different from the GTL specification, and is referred to as GTL+. For more information on GTL+ specifications, see the GTL+ buffer specification in the *Intel® Pentium® II Processor Developer's Manual*.

Current P6 family processors vary from the Pentium Pro processor in their output buffer implementation. The buffers that drive the system bus signals on the Celeron, Pentium II, and Pentium III processors are actively driven to V_{TT} for one clock cycle after the low to high transition to improve rise times. These signals should still be considered open-drain and require termination to a supply that provides the high signal level. Because this specification is different from the standard GTL+ specification, it is referred to as AGTL+, or Assisted GTL+ in this and other documentation. AGTL+ logic and GTL+ logic are compatible with each other and may both be used on the same system bus. For more information on AGTL+ routing, see the appropriate platform design guide.

Note that some Pentium III processors with CPUID 068xh support the AGTL specification in addition to the AGTL+ specification. AGTL logic and AGTL+ logic are not compatible with each other due to differences with the signal switching levels. Processors that do not support the AGTL specification cannot be installed into platforms where the chipset only supports the AGTL signal levels.   For more information on AGTL or AGTL+ routing, please refer to the appropriate platform design guide.

Both AGTL and AGTL+ inputs use differential receivers which require a reference signal (V_{REF}). V_{REF} is used by the receivers to determine if a signal is a logical 0 or a logical 1, and is supplied by the motherboard to the PGA370 socket for the processor core. Local V_{REF} copies should also be generated on the motherboard for all other devices on the AGTL+ (AGTL) system bus. Termination (usually a resistor at each end of the signal trace) is used to pull the bus up to the high voltage level and to control reflections on the transmission line. The processor contains on-die termination resistors that provide termination for one end of the bus, except for RESET#. These specifications assume another resistor at the end of each signal trace to ensure adequate signal quality for the AGTL+ (AGTL) signals and provide backwards compatibility for the Celeron processor; see Table 12 for the bus termination voltage specifications for AGTL+. Refer to the *Intel® Pentium® II Processor Developer's Manual* for the AGTL+ bus specification. Solutions exist for single-ended termination as well, though this implementation changes system design and eliminate backwards compatibility for Celeron processors in the PPGA package. Single-ended termination designs must still provide an AGTL+ (AGTL) termination resistor on the motherboard for the RESET# signal. Figure 2 is a schematic representation of the AGTL+ (AGTL) bus topology for the Pentium III processors in the PGA370 socket. Figure 3 is a schematic representation of the AGTL+/AGTL bus topology in a dual-processor configuration with Pentium III processors in the PGA370 socket.

Both AGTL+ and AGTL bus depend on incident wave switching. Therefore, timing calculations for AGTL+ or AGTL signals are based on flight time as opposed to capacitive deratings. Analog signal simulation of the system bus including trace lengths is highly recommended when designing a

system with a heavily loaded AGTL+ bus, especially for systems using a single set of termination resistors (i.e., those on the processor die). Such designs will not match the solution space allowed for by installation of termination resistors on the baseboard.

Figure 2. AGTL+/AGTL Bus Topology in a Uniprocessor Configuration
Figure 3. AGTL+/AGTL Bus Topology in a Dual-Processor Configuration
2.2 Clock Control and Low Power States

Processors allow the use of AutoHALT, Stop-Grant, Sleep, and Deep Sleep states to reduce power consumption by stopping the clock to internal sections of the processor, depending on each particular state. See Figure 4 for a visual representation of the processor low-power states.

Figure 4. Stop Clock State Machine
For the processor to fully realize the low current consumption of the Stop-Grant, Sleep and Deep Sleep states, a Model Specific Register (MSR) bit must be set. For the MSR at 02AH (Hex), bit 26 must be set to a '1' (this is the power on default setting) for the processor to stop all internal clocks during these modes. For more information, see the *Intel Architecture Software Developer's Manual, Volume 3: System Programming Guide* located on the developer.intel.com website.

2.2.1   Normal State—State 1

This is the normal operating state for the processor.

2.2.2   AutoHALT Powerdown State—State 2

AutoHALT is a low power state entered when the processor executes the HALT instruction. The processor transitions to the Normal state upon the occurrence of SMI#, INIT#, or LINT[1:0] (NMI, INTR). RESET# causes the processor to immediately initialize itself.

The return from a System Management Interrupt (SMI) handler can be to either Normal Mode or the AutoHALT Power Down state. See the *Intel Architecture Software Developer's Manual, Volume III: System Programmer's Guide* for more information.

FLUSH# is serviced during the AutoHALT state, and the processor will return to the AutoHALT state.

The system can generate a STPCLK# while the processor is in the AutoHALT Power Down state. When the system deasserts the STPCLK# interrupt, the processor returns execution to the HALT state.

2.2.3 Stop-Grant State—State 3

The Stop-Grant state on the processor is entered when the STPCLK# signal is asserted.

Since the AGTL+ signal pins receive power from the system bus, these pins should not be driven (allowing the level to return to V_{TT}) for minimum power drawn by the termination resistors in this state. In addition, all other input pins on the system bus should be driven to the inactive state.

BINIT# and FLUSH# are not serviced during the Stop-Grant state.

RESET# causes the processor to immediately initialize itself, but the processor stays in Stop-Grant state. A transition back to the Normal state occurs with the deassertion of the STPCLK# signal.

A transition to the HALT/Grant Snoop state occurs when the processor detects a snoop on the system bus (see Section 2.2.4). A transition to the Sleep state (see Section 2.2.5) occurs with the assertion of the SLP# signal.

While in Stop-Grant State, SMI#, INIT#, and LINT[1:0] are latched by the processor, and only serviced when the processor returns to the Normal state. Only one occurrence of each event is recognized and serviced upon return to the Normal state.

2.2.4 HALT/Grant Snoop State—State 4

The processor responds to snoop transactions on the system bus while in Stop-Grant state or in AutoHALT Power Down state. During a snoop transaction, the processor enters the HALT/Grant Snoop state. The processor stays in this state until the snoop on the system bus has been serviced (whether by the processor or another agent on the system bus). After the snoop is serviced, the processor returns to the Stop-Grant state or AutoHALT Power Down state, as appropriate.

2.2.5 Sleep State—State 5

The Sleep state is a very low power state in which the processor maintains its context, maintains the phase-locked loop (PLL), and has stopped all internal clocks. The Sleep state can only be entered from the Stop-Grant state. Once in the Stop-Grant state, the SLP# pin can be asserted, causing the processor to enter the Sleep state. The SLP# pin is not recognized in the Normal or AutoHALT states.

Snoop events that occur while in Sleep state or during a transition into or out of Sleep state will cause unpredictable behavior.

In the Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions or assertions of signals (with the exception of SLP# or RESET#) are allowed on the system bus while the processor is in Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behavior.

If RESET# is driven active while the processor is in the Sleep state, and held active as specified in the RESET# pin specification, then the processor will reset itself, ignoring the transition through Stop-Grant State. If RESET# is driven active while the processor is in the Sleep State, the SLP# and STPCLK# signals should be deasserted immediately after RESET# is asserted to ensure the processor correctly executes the reset sequence.

While in the Sleep state, the processor is capable of entering its lowest power state, the Deep Sleep state, by stopping the BCLK input (see Section 2.2.6). Once in the Sleep or Deep Sleep states, the SLP# pin can be deasserted if another asynchronous system bus event occurs. The SLP# pin has a minimum assertion of one BCLK period.

2.2.6 Deep Sleep State—State 6

The Deep Sleep state is the lowest power state the processor can enter while maintaining context. The Deep Sleep state is entered by stopping the BCLK[1] input (after the Sleep state was entered from the assertion of the SLP# pin). The processor is in Deep Sleep state immediately after BCLK is stopped. It is recommended that the BCLK[1] input be held low during the Deep Sleep State. Stopping of the BCLK[1] input lowers the overall current consumption to leakage levels.

To re-enter the Sleep state, the BCLK input must be restarted. A period of 1 ms (to allow for PLL stabilization) must occur before the processor can be considered to be in the Sleep state. Once in the Sleep state, the SLP# pin can be deasserted to re-enter the Stop-Grant state.

While in Deep Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions or assertions of signals are allowed on the system bus while the processor is in Deep Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behavior.

2.2.7 Clock Control

BCLK[2] provides the clock signal for the processor and on die L2 cache. During AutoHALT Power Down and Stop-Grant states, the processor will process a system bus snoop. The processor does not stop the clock to the L2 cache during AutoHALT Power Down or Stop-Grant states. Entrance into the Halt/Grant Snoop state allows the L2 cache to be snooped, similar to the Normal state.

When the processor is in Sleep and Deep Sleep states, it does not respond to interrupts or snoop transactions. During the Sleep state, the internal clock to the L2 cache is not stopped. During the Deep Sleep state, the internal clock to the L2 cache is stopped. The internal clock to the L2 cache is restarted only after the internal clocking mechanism for the processor is stable (i.e., the processor has re-entered Sleep state).

PICCLK should not be removed during the AutoHALT Power Down or Stop-Grant states. PICCLK can be removed during the Sleep or Deep Sleep states. When transitioning from the Deep Sleep state to the Sleep state, PICCLK must be restarted with BCLK.[2]

2.3 Power and Ground Pins

The operating voltage of the Pentium III processor for the PGA370 socket is the same for the core and the L2 cache; VCC_{CORE}. There are four pins defined on the package for voltage identification (VID). These pins specify the voltage required by the processor core. These have been added to cleanly support voltage specification variations on current and future processors.

For clean on-chip power and voltage reference distribution, the Pentium III processors in the PGA370 socket have 75 VCC_{CORE}, 8 V_{REF} (7 for AGTL platforms), 15 V_{TT}, and 77 V_{SS} (ground) inputs. VCC_{CORE} inputs supply the processor core, including the on-die L2 cache. V_{TT} inputs

---

1. For processors using AGTL level bus with differential clocking, the deep sleep state is entered by stopping BCLK and BCLK# input.
2. For processors using AGTL level bus with differential clocking this would also include the BCLK# signal as well.

(1.5 V/1.25 V) are used to provide an AGTL+/AGTL termination voltage to the processor, and the V_{REF} inputs are used as the AGTL+/AGTL reference voltage for the processor. Note that not all VTT inputs must be connected to the VTT supply. Refer to Section 5.4 for more details.

On the motherboard, all VCC_{CORE} pins must be connected to a voltage island (an island is a portion of a power plane that has been divided, or an entire plane). In addition, the motherboard must implement the VTT pins as a voltage island or large trace. Similarly, all GND pins must be connected to a system ground plane.

Three additional power related pins exist on a processors utilizing the PGA370 socket. They are $VCC_{1.5}$, $VCC_{2.5}$ and VCC_{CMOS}.

The VCC_{CMOS} pin provides the CMOS voltage for the pull-up resistors required on the system platform. A 2.5 V source must be provided to the $VCC_{2.5}$ pin and a 1.5 V source must be provided to the $VCC_{1.5}$ pin. The source for $VCC_{1.5}$ must be the same as the one supplying VTT. The processor routes the compatible CMOS voltage source (1.5 V or 2.5 V) through the package and out to the VCC_{CMOS} output pin. Processors based on 0.25 micron technology (e.g., the Celeron processor) utilize 2.5 V CMOS buffers. Processors based on 0.18 micron technology (e.g., the Pentium III processor for the PGA370 socket) utilize 1.5 V CMOS buffers. The signal $VCORE_{DET}$ can be used by hardware on the motherboard to detect which CMOS voltage the processor requires. A $VCORE_{DET}$ connected to VSS within the processor indicates a 1.5 V requirement on VCC_{CMOS}. Refer to Figure 5.

Each power signal must meet the specifications stated in Table 7 on page 28.

Figure 5. Processor VCC$_{CMOS}$ Package Routing
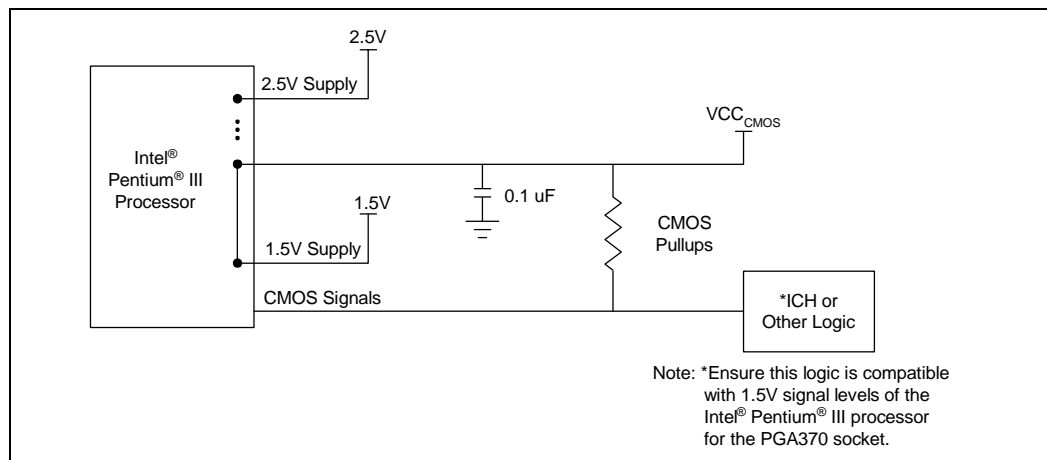

2.3.1 Phase Lock Loop (PLL) Power

It is highly critical that phase lock loop power delivery to the processor meets Intel's requirements. A low pass filter is required for power delivery to pins PLL1 and PLL2. This serves as an isolated, decoupled power source for the internal PLL. Please refer to the Phase Lock Loop Power section in the **appropriate platform design guide** for the recommended filter specifications.

2.4   Decoupling Guidelines

Due to the large number of transistors and high internal clock speeds, the processor is capable of generating large average current swings between low and full power states. The fluctuations can cause voltages on power planes to sag below their nominal values if bulk decoupling is not adequate. Care must be taken in the board design to ensure that the voltage provided to the processor remains within the specifications listed in Table 7. Failure to do so can result in timing violations (in the event of a voltage sag) or a reduced lifetime of the component (in the event of a voltage overshoot). **Unlike SC242 based designs, motherboards utilizing the PGA370 socket must provide high frequency decoupling capacitors on all power planes for the processor.**

2.4.1   Processor $V_{CC_{CORE}}$ and AGTL+ (AGTL) Decoupling

The regulator for the $V_{CC_{CORE}}$ input must be capable of delivering the $dI_{CC_{CORE}}/dt$ (defined in Table 7) while maintaining the required tolerances (also defined in Table 7). Failure to meet these specifications can result in timing violations (during $V_{CC_{CORE}}$ sag) or a reduced lifetime of the component (during $V_{CC_{CORE}}$ overshoot).

The processor requires both high frequency and bulk decoupling on the system motherboard for proper AGTL+ (AGTL) bus operation. See the AGTL+ buffer specification in the *Intel® Pentium® II Processor Developer's Manual* for more information. Also, refer to the appropriate platform design guide for recommended capacitor component placement. The minimum recommendation for the processor decoupling is listed below. All capacitors should be placed within the PGA370 socket cavity and mounted on the primary side of the motherboard. The capacitors are arranged to minimize the overall inductance between the $V_{CC_{CORE}}$ and Vss power pins.

1. $V_{CC_{CORE}}$ decoupling - 4.7 µF capacitors in a 1206 package.

2. V_{TT} decoupling - 0.1 µF capacitors in 0603 package.

3. V_{REF} decoupling - 0.1 µF and 0.001 µF capacitors in 0603 package placed near the V_{REF} pins.

For additional decoupling requirements, please refer to the appropriate platform design guide for recommended capacitor component value, quantity and placement.

2.5   Processor System Bus Clock and Processor Clocking

The BCLK input directly controls the operating speed of the system bus interface. All AGTL+/AGTL system bus timing parameters are specified with respect to the rising edge of the BCLK input.

The Coppermine-T processor will implement an auto-detect mechanism that will let the processor use either single-ended or differential signaling for the system bus and processor clocking. The processor checks to see if the signal on pin Y33 is toggling. If this signal is toggling then the processor operates in differential mode. Refer to Figure 6 for a differential clocking example. Resistor values and clock topology are listed in the appropriate platform design guide for a differential implementation.

Note: References to BCLK throughout this document will also imply to its complement signal, BCLK#, in differential implementations and when noted otherwise.

For a differential clock input, all AGTL system bus timing parameters are specified with respect to the crossing point of the rising edge of the BCLK input and the falling edge of the BCLK# input. See the *P6 Family of Processors Hardware Developer's Manual* for further details.

Note: For differential clocking, the reference voltage of the BCLK in the *P6 Family of Processors Hardware Developer's Manual* is re-defined as the crossing point of the BCLK and the BCLK# inputs.

Figure 6. Differential Clocking Example
2.5.1 Mixing Processors of Different Frequencies

In two-way MP (multi-processor) systems, mixing processors of different internal clock frequencies is not supported and has not been validated. Pentium III processors do not support a variable multiplier ratio; therefore, adjusting the ratio setting to a common clock frequency is not valid. However, mixing processors of the same frequency but of different steppings is supported. Details on support for mixed steppings is provided in the *Pentium® III Processor Specification Update*.

Note: Not all Pentium III processors for the PGA370 socket are validated for use in dual processor (DP) systems. Refer to the *Pentium® III Processor Specification Update* to determine which processors are DP capable.

2.6 Voltage Identification

There are four voltage identification pins on the PGA370 socket. These pins can be used to support automatic selection of $V_{CC_{CORE}}$ voltages. These pins are not signals, but are either an open circuit or a short circuit to V_{SS} on the processor. The combination of opens and shorts defines the voltage required by the processor core. The VID pins are needed to cleanly support voltage specification variations on current and future processors. VID[3:0] are defined in Table 2. A '1' in this table refers to an open pin and a '0' refers to a short to ground. The voltage regulator or VRM must supply the voltage that is requested or disable itself.

To ensure a system is ready for current and future processors, the range of values in **bold** in Table 2 should be supported. A smaller range will risk the ability of the system to migrate to a higher performance processor and/or maintain compatibility with current processors.

Table 2. Voltage Identification Definition [1, 2]

VID3	VID2	VID1	VID0	Vcc$_{CORE}$
1	1	1	1	**1.30**
1	1	1	0	**1.35**

0	0	1	1	1.90[3]
0	0	1	0	1.95[3]
0	0	0	1	2.00[3]
0	0	0	0	2.05[3]
1	1	1	1	**No Core**

NOTES:
1. 0 = Processor pin connected to V$_{SS}$.
2. 1 = Open on processor; may be pulled up to TTL V$_{IH}$ on baseboard.
3. To ensure a system is ready for the Pentium III and Celeron processors, the values in **BOLD** in Table 2 should be supported.

Note that the '1111' (all opens) ID can be used to detect the absence of a processor core in a given socket as long as the power supply used does not affect these lines. Detection logic and pull-ups should not affect VID inputs at the power source (see Section 7.0).

The VID pins should be pulled up to a TTL-compatible level with external resistors to the power source of the regulator only if required by the regulator or external logic monitoring the VID[3:0] signals. The power source chosen must be guaranteed to be stable whenever the supply to the voltage regulator is stable. This will prevent the possibility of the processor supply going above the specified VCC$_{CORE}$ in the event of a failure in the supply for the VID lines. In the case of a DC-to-DC converter, this can be accomplished by using the input voltage to the converter for the VID line pull-ups. A resistor of greater than or equal to 10 kΩ may be used to connect the VID signals to the converter input. Note that no changes have been made to the physical connector or pin definitions between the Intel-enabled VRM 8.2 and VRM 8.4 specifications.

Note: VRM 8.5 specification uses five VID pin assignments VID[3:0, 25mV] and it is not compatible with VRM 8.4. Some Pentium III processors with CPUID 068xh are capable of supporting both VRM 8.4 and VRM 8.5 specifications. Please refer to the *Pentium III Specification Update* for a listing of processors that support both VRM specifications.

2.7 Processor System Bus Unused Pins

All RESERVED pins must remain unconnected unless specifically noted. Connection of these pins to VCC_{CORE}, V_{REF}, VSS, VTT, or to any other signal (including each other) can result in component malfunction or incompatibility with future processors. See Section 5.4 for a pin listing of the processor and the location of each RESERVED pin.

PICCLK must be driven with a valid clock input and the PICD[1:0] signals must be pulled-up to VCC_{CMOS} even when the APIC will not be used. A separate pull-up resistor must be provided for each PICD signal.

For reliable operation, always connect unused inputs or bidirectional signals to their deasserted signal level. The pull-up or pull-down resistor values are system dependent and should be chosen such that the logic high (V_{IH}) and logic low (V_{IL}) requirements are met. See Table 10 and Table 11 for DC specifications of non-AGTL+/AGTL signals.

Unused AGTL+ (or AGTL) inputs must be properly terminated to VTT on PGA370 socket motherboards which support the Celeron and the Pentium III processors. For designs that intend to only support the Pentium III processor, unused AGTL+ inputs will be terminated by the processor's on-die termination resistors and thus do not need to be terminated on the motherboard. However, RESET# must always be terminated on the motherboard as the Pentium III processor for the PGA370 socket does not provide on-die termination of this input.

For unused CMOS inputs, active low signals should be connected through a pull-up resistor to VCC_{CMOS} and meet V_{IH} requirements. Unused active high CMOS inputs should be connected through a pull-down resistor to ground (VSS) and meet V_{IL} requirements. Unused CMOS outputs can be left unconnected. A resistor must be used when tying bidirectional signals to power or ground. When tying any signal to power or ground, a resistor will also allow for system testability.

2.8 Processor System Bus Signal Groups

To simplify the following discussion, the processor system bus signals have been combined into groups by buffer type. All P6 family processor system bus outputs are open drain and require a high-level source provided termination resistors. However, the Pentium III processor for the PGA370 socket includes on-die termination. **Motherboard designs that also support Celeron processors in the PPGA package will need to provide AGTL+ termination on the system motherboard as well. Platform designs that support dual processor configurations will need to provide AGTL+ termination, via a termination package, in any socket not populated with a processor. Please refer to the** *Pentium III Processor Specification Update* **for a complete listing of the processors that support the AGTL and AGTL+ specifications. Note that AGTL platforms do not support the Celeron processor in the PPGA package.**

Both AGTL+ and AGTL input signals have differential input buffers which use V_{REF} as a reference signal. AGTL+ output signals require termination to 1.5 V while AGTL output signals require termination to 1.25 V. In this document, the term "AGTL+ Input" refers to the AGTL+ input group as well as the AGTL+ I/O group when receiving. Similarly, "AGTL+ Output" refers to the AGTL+ output group as well as the AGTL+ I/O group when driving.

The PWRGOOD, BCLK, and PICCLK inputs can each be driven from ground to 2.5 V. Other CMOS inputs (A20M#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, PREQ#, SMI, SLP#, and STPCLK#) are only 1.5 V tolerant and must be pulled up to VCC_{CMOS}. The CMOS, APIC, and TAP outputs are open drain and must be pulled high to VCC_{CMOS}. This ensures correct operation for current Pentium III and Celeron processors.

The groups and the signals contained within each group are shown in Table 3 and Table 4. Refer to Section 7.0 for a description of these signals.

Table 3. System Bus Signal Groups [1]

Group Name	Signals
AGTL+ Input	BPRI#, BR1#[7], DEFER#, RESET# [6],RESET2#, RS[2:0]#, RSP#, TRDY#
AGTL+ Output	PRDY#
AGTL+ I/O	A[35:3]#, ADS#, AERR#, AP[1:0]#, BERR#, BINIT#, BNR#, BP[3:2]#, BPM[1:0]#, BR0#[2], D[63:0]#, DBSY#, DEP[7:0]#, DRDY#, HIT#, HITM#, LOCK#, REQ[4:0]#, RP#
CMOS Input[3]	A20M#, FLUSH#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, PREQ#, SLP#, SMI#, STPCLK#
CMOS Input[4]	PWRGOOD
CMOS Output[3]	FERR#, IERR#, THERMTRIP#
System Bus Clock[4]	BCLK
APIC Clock[4]	PICCLK
APIC I/O[3]	PICD[1:0]
Power/Other[5]	BSEL[1:0], CLKREF, CPUPRES#, EDGCTRL, PLL[2:1], RESET2#, SLEWCTRL, THERMDN, THERMDP, RTTCTRL[8], $Vcore_{DET}$, VID[3:0], $Vcc_{1.5}$, $Vcc_{2.5}$, Vcc_{CMOS}, Vcc_{CORE}, V_{REF}, Vss, V_{TT}, Reserved

NOTES:
1. See Section 7.0 for information on the these signals.
2. The BR0# pin is the only BREQ# signal that is bidirectional. See Section 7.0 for more information. The internal BREQ# signals are mapped onto the BR[1:0]# pins after the agent ID is determined.
3. These signals are specified for Vcc_{CMOS} (1.5 V for the Pentium III processor) operation.
4. These signals are 2.5 V tolerant.
5. Vcc_{CORE} is the power supply for the processor core and is described in Section 2.6.
   VID[3:0] is described in Section 2.6.
   V_{TT} is used to terminate the system bus and generate V_{REF} on the motherboard.
   Vss is system ground.
   $Vcc_{1.5}$, $Vcc_{2.5}$, Vcc_{CMOS} are described in Section 2.3.
   BSEL[1:0] is described in Section 2.8.2 and Section 7.0.
   All other signals are described in Section 7.0.
6. RESET# must always be terminated to V_{TT} on the motherboard, on-die termination is not provided for this signal.
7. This signal is not supported by all processors. Refer to the *Pentium® III Processor Specification Update* for a complete listing of processors that support this pin.
8. This signal is used to control the value of the processor on-die termination resistance. Refer to the platform design guide for the recommended pull-down resistor value.

Table 4. System Bus Signal Groups (AGTL)[1] (Sheet 1 of 2)

Group Name	Signals
AGTL Input[9]	BPRI#, BR1#[7], DEFER#, RESET#[6], RSP#, TRDY#, RS[2:0]#
AGTL Output[9]	PRDY#
AGTL I/O[9]	A[35:3]#, ADS#, AERR#, AP[1:0]#, BERR#, BINIT#, BNR#, BP[3:2]#, BPM[1:0]#, BR0#[2], D[63:0]#, DBSY#, DEP[7:0]#, DRDY#, HIT#, HITM#, LOCK#, REQ[4:0]#, RP#,
CMOS Input[3]	A20M#, FLUSH#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, PREQ#, SLP#, SMI#, STPCLK#
CMOS Input (1.8 V)	PWRGOOD
CMOS Output	FERR#[3], IERR#[3], THERMTRIP#[3], VID[3:0][13], BSEL[1:0][13]

Table 4. System Bus Signal Groups (AGTL)[1] (Sheet 2 of 2)

Group Name	Signals
System Bus Clock[10, 12] (1.25 V/2.5 V)	BCLK, BCLK0#
APIC Clock (2.0 V)	PICCLK[11]
APIC I/O[3]	PICD[1:0]
Power/Other[5]	BSEL[1:0], CLKREF[10], CPUPRES#, EDGCTRL, PLL[2:1], RESET2#, SLEWCTRL, THERMDN, THERMDP, RTTCTRL[8], $VCORE_{DET}$, VID[3:0], $Vcc_{1.5}$, $Vcc_{2.5}$, Vcc_{CMOS}, Vcc_{CORE}, V_{REF}, Vss, VTT, Reserved

NOTES:
1. See Section 7.0 for information on the these signals.
2. The BR0# pin is the only BREQ# signal that is bidirectional. See Section 7.0 for more information. The internal BREQ# signals are mapped onto the BR[1:0]# pins after the agent ID is determined.
3. These signals are specified for Vcc_{CMOS} (1.5 V for the Pentium III processor) operation.
4. These signals are 2.5 V tolerant.
5. Vcc_{CORE} is the power supply for the processor core and is described in Section 2.6.
   VID[3:0] is described in Section 2.6.
   VTT is used to terminate the system bus and generate V_{REF} on the motherboard.
   Vss is system ground.
   $Vcc_{1.5}$, $Vcc_{2.5}$, Vcc_{CMOS} are described in Section 2.3.
   BSEL[1:0] is described in Section 2.8.2 and Section 7.0.
   All other signals are described in Section 7.0.
6. RESET# must always be terminated to VTT on the motherboard, on-die termination is not provided for this signal.
7. This signal is not supported by all processors. Refer to the *Pentium® III Processor Specification Update* for a complete listing of processors that support this pin.
8. This signal is used to control the value of the processor on-die termination resistance. Refer to the platform design guide for the recommended pull-down resistor value.
9. These signals are also classified as AGTL. Refer to the *Pentium® III Processor Specification Update* for a complete listing of processors that support the AGTL and AGTL+ specifications.
10. For differential clock systems, the CLKREF pin becomes BCLK#.
11. For the Coppermine-T differential clock, this signal has been redefined to 2.0 V tolerant.
12. 1.25 V signal for Differential clock application and 2.5 V for Single-ended clock application.
13. This signal is 3.3 V.

2.8.1 Asynchronous vs. Synchronous for System Bus Signals

All AGTL+ signals are synchronous to BCLK. All of the CMOS, Clock, APIC, and TAP signals can be applied asynchronously to BCLK. All APIC signals are synchronous to PICCLK.

2.8.2   System Bus Frequency Select Signals (BSEL[1:0])

These signals are used to select the system bus frequency for the processor. The BSEL signals are also used by the chipset and system bus clock generator. Table 5 defines the possible combinations of the signals and the frequency associated with each combination. The frequency selection is determined by the processor(s) and driven out to the chipset and clock generator. All system bus agents must operate at the same frequency determined by the processor. **The Pentium III processor for the PGA370 socket operates at 100 MHz or 133 MHz system bus frequency; 66 MHz system bus operation is not supported**. Individual processors will only operate at their specified front side bus (FSB) frequency, either 100 MHz or 133 MHz, not both. Over or under-clocking the system bus frequency outside the specified rating marked on the package is not recommended.

On motherboards that support operation at either 100 MHz or 133 MHz, the BSEL1 signal must be pulled up to a logic high by a resistor located on the motherboard and provided as a frequency selection signal to the clock driver/synthesizer. This signal can also be incorporated into RESET# logic on the motherboard if only 133 MHz operation is supported (thus forcing the RESET# signal to remain active as long as the BSEL1 signal is low.

The BSEL0 signal will float from the processor and should be pulled up to a logic high by a resistor located on the motherboard. The BSEL0 signal can be incorporated into RESET# logic on the motherboard if 66 MHz operation is unsupported, as demonstrated in Figure 7. Refer to the appropriate clock synthesizer design guidelines and platform design guide for more details on the bus frequency select signals.

In a 2-way MP system design, these BSEL[1:0] signals must connect the pins of both processors.

Figure 7. BSEL[1:0] Example for a 100/133 MHz or 100 MHz Only System Design
NOTES:
1. Some clock drivers may require a series resistor on their BSEL1 input.
2. Some chipsets may connect to the BSEL[1:0] signals and require a series resistor. See the appropriate platform design guide for implementation details.

Table 5.   Frequency Select Truth Table for BSEL[1:0]

BSEL1	BSEL0	Frequency
0	0	66 MHz (unsupported)
0	1	100 MHz
1	0	Reserved
1	1	133 MHz

2.9   Maximum Ratings

Table 6 contains processor stress ratings only. Functional operation at the absolute maximum and minimum is not implied nor guaranteed. The processor should not receive a clock while subjected to these conditions. Functional operating conditions are given in the AC and DC tables in Section 2.10 through Section 2.12. Extended exposure to the maximum ratings may affect device reliability. Furthermore, although the processor contains protective circuitry to resist damage from static electric discharge, one should always take precautions to avoid high static voltages or electric fields.

Table 6.   Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Unit	Notes
$T_{STORAGE}$	Processor storage temperature	−40	85	°C	
Vcc_{CORE} and V_{TT}	Processor core voltage and termination supply voltage with respect to V_{SS}	−0.5	2.1	V	
Vin_{AGTL}	AGTL+ buffer input voltage	V_{TT} - 2.18	2.18	V	1, 2
$Vin_{CMOS}1.5$	CMOS buffer DC input voltage with respect to V_{SS}	V_{TT} - 2.18	2.18	V	1, 2, 3
$Vin_{CMOS}2.5$	CMOS buffer DC input voltage with respect to V_{SS}	-0.58	3.18	V	4
I_{VID}	Max VID pin current	-0.3	5	mA	
$I_{CPUPRES\#}$	Max CPUPRES# pin current		5	mA	

NOTES:
1. Input voltage can never exceed V_{SS} + 2.18 V.
2. Input voltage can never go below V_{TT} - 2.18 V.
3. Parameter applies to CMOS (except BCLK, PICCLK, and PWRGOOD) and APIC bus signal groups only.
4. Parameter applies to CMOS signals BCLK, PICCLK, and PWRGOOD only.

2.10   Processor DC Specifications

The processor DC specifications in this section are defined at the PGA370 socket pins (bottom side of the motherboard). See Section 7.0 for the processor signal descriptions and Section 5.4 for the signal listings.

Most of the signals on the processor system bus are in the AGTL+ (AGTL) signal group. These signals are specified to be terminated to 1.5 V for AGTL+ or 1.25 V for AGTL. The DC specifications for these signals are listed in Table 9 on page 34.

To allow connection with other devices, the clock, CMOS, and APIC signals are designed to interface at non-AGTL+ levels. The DC specifications for these pins are listed in Table 11 on page 35.

Table 7 through Table 12 list the DC specifications for the Pentium III processor for the PGA370 socket. Specifications are valid only while meeting specifications for junction temperature, clock frequency, and input voltages. Care should be taken to read all notes associated with each parameter.

dI_{VTT}/dt	Termination current slew rate					8	A/μs	12, 13, See Table 12

NOTES:
1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. All specifications in this table apply only to the Pentium III processor. For motherboard compatibility with the Celeron processor, see the *Intel® Celeron™ Processor Datasheet*.
3. Vcc_{CORE} and Icc_{CORE} supply the processor core and the on-die L2 cache.
4. Use the "typical voltage" specification with the "tolerance specifications" to provide correct voltage regulation to the processor.
5. V_{TT} and $Vcc_{1.5}$ must be held to 1.5 V ±9% while the AGTL+ bus is active. It is required that V_{TT} and $Vcc_{1.5}$ be held to 1.5 V ±3% while the processor system bus is static (idle condition). The ±3% range is the required design target; ±9% will come from the transient noise added. This is measured at the PGA370 socket pins on the bottom side of the baseboard.
6. **These are the tolerance requirements, across a 20 MHz frequency bandwidth, measured at the processor socket pin on the soldered-side of the motherboard.** Vcc_{CORE} must return to within the static voltage specification within 100 μs after a transient event; see the *VRM 8.4 DC-DC Converter Design Guidelines* for further details.
7. V_{REF} should be generated from V_{TT} by a voltage divider of 1% resistors or 1% matched resistors. Refer to the *Intel® Pentium® II Processor Developer's Manual* for more details on V_{REF}.
8. Maximum Icc is measured at V_{CC} typical voltage and under a maximum signal loading conditions.
9. Voltage regulators may be designed with a minimum equivalent internal resistance to ensure that the output voltage, at maximum current output, is no greater than the nominal (i.e., typical) voltage level of Vcc_{CORE} (Vcc_{CORE_TYP}). In this case, the maximum current level for the regulator, Icc_{CORE_REG}, can be reduced from the specified maximum current Icc_{CORE_MAX} and is calculated by the equation:

$$Icc_{CORE\_REG} = Icc_{CORE\_MAX} \times (Vcc_{CORE\_TYP} - Vcc_{CORE\_STATIC\_TOLERANCE}) / Vcc_{CORE\_TYP}$$

10. The current specified is the current required for a single processor. A similar amount of current is drawn through the termination resistors on the opposite end of the AGTL+ bus, unless single-ended termination is used (see Section 2.1).
11. The current specified is also for AutoHALT state.
12. Maximum values are specified by design/characterization at nominal Vcc_{CORE}.
13. Based on simulation and averaged over the duration of any change in current. Use to compute the maximum inductance tolerable and reaction time of the voltage regulator. This parameter is not tested.
14. dIcc/dt specifications are measured and specified at the PGA370 socket pins.
15. CLKREF must be held to 1.25 V ±6.5%. This tolerance accounts for a ±5% power supply and ±1% resistor divider tolerance. It is recommended that the motherboard generate the CLKREF reference from either the 2.5 V or 3.3 V supply. V_{TT} should not be used due to risk of AGTL+ switching noise coupling to this analog reference.
16. Static voltage regulation includes: DC output initial voltage set point adjust, Output ripple and noise, Output load ranges specified in the tables above.
17. This specification applies to PGA370 processors operating at frequencies of 933 MHz or higher.

18. This specification only applies to 1B GHz S-spec #: SL4WM. This part has a VID request of 1.70 V, however the processor should be supplied 1.76 V at the PGA Vcc pin by the Voltage Regulator Circuit or VRM.
19. This specification applies only to 1B GHz S-spec #: SL4WM. This value is 60 mV offset from the standard specification and more at the Minimum specification. These tolerances are measured from a 1.70 V base, while Vcc supplied is 1.76 V.
20. This processor exists in both FC-PGA and FC-PGA2.

2.10.1 ICC Slew Rate Specifications

This section contains typical current slew rate data for processors covered by this design guideline. Actual slew rate values and wave-shapes may vary slightly depending on the type and size of decoupling capacitors used in a particular implementation.

Figure 8. Slew Rate (23A Load Step)
Table 8. PL Slew Rate Data (23A) (Sheet 1 of 2)

Time (μs)	Icc (A)
0.1	9.55
0.15	14.4
0.5	20.85
1	23.04
1.5	23.44
2	23.28
2.5	22.32
3	21.63
3.5	21.45
4	21.63

Table 8. PL Slew Rate Data (23A) (Sheet 2 of 2)

Time (μs)	Icc (A)
4.5	21.88
5	22.01

Table 9. AGTL / AGTL+ Signal Groups DC Specifications [1]

Symbol	Parameter	Min	Max	Unit	Notes
V_{IL}	Input Low Voltage	−0.150	V_{REF} - 0.200	V	6
V_{IH}	Input High Voltage	V_{REF} + 0.200	V_{TT}	V	2, 3, 6
Ron	Buffer On Resistance		16.67	Ω	5
I_L	Leakage Current for inputs, outputs, and I/O		±100	μA	4

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors at all frequencies.
2. All inputs, outputs, and I/O pins must comply with the signal quality specifications in Section 3.0.
3. Minimum and maximum V_{TT} are given in Table 12 on page 36.
4. (0 ≤ V_{IN} ≤ 1.5 V +3%) and (0≤V_{OUT}≤1.5 V+3%).
5. Refer to the processor I/O Buffer Models for I/V characteristics.
6. Steady state input voltage must not be above V_{SS} + 1.65 V or below V_{TT} - 1.65 V.

Table 10. Non-AGTL+ Signal Group DC Specifications [1]

Symbol	Parameter	Min	Max	Unit	Notes
$V_{IL1.5}$	Input Low Voltage	-0.150	V_{CMOS_REF} - 0.200	V	9
$V_{IL2.5}$	Input Low Voltage	-0.58	0.700	V	5, 8
$V_{IH1.5}$	Input High Voltage	V_{CMOS_REF} + 0.200	1.5	V	6, 9
$V_{IH2.5}$	Input High Voltage	2.000	3.18	V	5, 8
V_{OL}	Output Low Voltage		0.400	V	2
R_{on}			35		2
V_{OH}	Output High Voltage		1.5	V	7, 9, All outputs are open-drain
I_{OL}	Output Low Current	9		mA	
I_{LI}	Input Leakage Current		±100	μA	3, 6
I_{LO}	Output Leakage Current		±100	μA	4, 7

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors at all frequencies.
2. Parameter measured at 9 mA (for use with TTL inputs).
3. (0 ≤ V_{IN} ≤ 2.5 V +5%).
4. (0 ≤ V_{OUT} ≤ 2.5 V +5%).
5. For BCLK specifications, refer to Table 24 on page 51.
6. (0 ≤ V_{IN} ≤ 1.5 V +3%).
7. (0 ≤ V_{OUT} ≤ 1.5 V +3%).
8. Applies to non-AGTL signals except BCLK, PICCLK, and PWRGOOD.
9. Applies to non-AGTL signals **except** BCLK, PICCLK, and PWRGOOD.

Table 11. Non-AGTL Signal Group DC Specifications [1]

Symbol	Parameter	Min	Max	Unit	Notes
$V_{IL1.5}$	Input Low Voltage	-0.150	V_{CMOS_REF} - 0.300	V	7, 8
$V_{IL2.5}$	Input Low Voltage	-0.58	0.700	V	4, 6
$V_{IH1.5}$	Input High Voltage	V_{CMOS_REF} + 0.200	1.5	V	5, 7
$V_{IH2.5}$	Input High Voltage	2.000	3.18	V	4, 6
V_{OL}	Output Low Voltage		0.300	V	2
R_{on}			35		2
V_{OH}	Output High Voltage		1.5	V	5, 7, All outputs are open-drain
I_{OL}	Output Low Current	9		mA	
I_{LI}	Input Leakage Current		±100	µA	3, 5
I_{LO}	Output Leakage Current		±100	µA	3, 5

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors at all frequencies.
2. Parameter measured at 9 mA (for use with TTL inputs).
3. ($0 \leq V_{IN} \leq 2.5$ V +5%); ($0 \leq V_{OUT} \leq 2.5$ V +5%).
4. For BCLK specifications, refer to Table 24 on page 51.
5. ($0 \leq V_{IN} \leq 1.5$ V +3%); ($0 \leq V_{OUT} \leq 1.5$ V +3%).
6. Applies to non-AGTL+ signals **except** BCLK, PICCLK, and PWRGOOD.
7. Applies to non-AGTL+ signals **except** BCLK, PICCLK, and PWRGOOD.
8. For Coppermine-T differential clocking, the input low voltage is (VCMOS_REF - 0.300)V.

2.11   AGTL / AGTL+ System Bus Specifications

It is recommended that the AGTL+ bus be routed in a daisy-chain fashion with termination resistors to V_{TT}. These termination resistors are placed electrically between the ends of the signal traces and the V_{TT} voltage supply and generally are chosen to approximate the system platform impedance. The valid high and low levels are determined by the input buffers using a reference voltage called V_{REF}. Refer to the appropriate platform design guide for more information

Table 12 below lists the nominal specification for the AGTL+ termination voltage (V_{TT}). The AGTL+ reference voltage (V_{REF}) is generated on the system motherboard and should be set to 2/3 V_{TT} for the processor and other AGTL+ logic. It is important that the baseboard impedance be specified and held to a ±15% tolerance, and that the intrinsic trace capacitance for the AGTL+ signal group traces is known and well-controlled. For more details on the AGTL+ buffer specification, see the *Intel® Pentium® II Processor Developer's Manual* and AP-585, *Intel® Pentium® II Processor AGTL+ Guidelines*.

Table 12. Processor AGTL+ Bus Specifications [1, 2]

Symbol	Parameter	Min	Typ	Max	Units	Notes
V_{TT}	Bus Termination Voltage		1.50		V	3
On-die R_{TT}	Termination Resistor	40		130	Ω	4
V_{REF}	Bus Reference Voltage	0.950	2/3 V_{TT}	1.05	V	5

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors at all frequencies.
2. Pentium III processors for the PGA370 socket contain AGTL+ termination resistors on the processor die, except for the RESET# input.
3. V_{TT} and $Vcc_{1.5}$ must be held to 1.5 V ±9%. It is required that V_{TT} and $Vcc_{1.5}$ be held to 1.5 V ±3% while the processor system bus is idle (static condition). This is measured at the PGA370 socket pins on the bottom side of the baseboard.
4. The value of the on-die R_{TT} is determined by the resistor value measured by the RTTCTRL signal pin. See Section 7.0 for more details on the RTTCTRL signal. Refer to the recommendation guidelines for the specific chipset/processor combination.
5. V_{REF} is generated on the motherboard and should be 2/3 V_{TT} ±2% nominally. Insure that there is adequate V_{REF} decoupling on the motherboard.

Table 13. Processor AGTL Bus Specifications [1, 2]

Symbol	Parameter	Min	Typ	Max	Units	Notes
V_{TT}	Bus Termination Voltage	1.14	1.25	1.308	V	3
On-die R_{TT}	Termination Resistor	50^6	56, 68	115	Ω	4, 7
V_{REF}	Bus Reference Voltage	2/3 V_{TT} - 2%	2/3 V_{TT}	2/3 V_{TT} + 2%	V	5

NOTES:
1. Specifications in this table do not apply to Pentium III processors at all frequencies. Please refer to the *Intel® Pentium® III Processor Specification Update* for a complete listing on the processors that support the AGTL specification.
2. Pentium III processors for the PGA370 socket contain AGTL termination resistors on the processor die, except for the RESET# input.
3. V_{TT} must be held to 1.25 V ±9%. It is required that V_{TT} be held to 1.25 V ±3% while the processor system bus is idle (static condition). This is measured at the PGA370 socket pins on the bottom side of the baseboard.
4. The value of the on-die R_{TT} is determined by the resistor value measured by the RTTCTRL signal pin. The on-die R_{TT} has a resistance tolerance of ±15%. See Section 7.0 for more details on the RTTCTRL signal. Refer to the recommendation guidelines for the specific chipset/processor combination.
5. V_{REF} is generated on the motherboard and should be 2/3 V_{TT} ±2% nominally. Insure that there is adequate V_{REF} decoupling on the motherboard.
6. For the Coppermine-T differential clock platform, the on-die RTT min should be 50 Ω.
7. Coppermine-T UP platforms require a 56Ω resistor and Coppermine-T DP platforms require a 68Ω resistor. Tolerance for the on-die R_{TT} is ±10% for 56Ω and 68Ω resistors and ±15% for 100 Ω resistors

2.12 System Bus AC Specifications

The processor system bus timings specified in this section are defined at the socket pins on the bottom of the motherboard. Unless otherwise specified, timings are tested at the processor pins during manufacturing. Timings at the processor pins are specified by design characterization. See Section 7.0 for the processor signal definitions.

Table 14 through Table 20 list the AC specifications associated with the processor system bus. These specifications are placed into the following categories: Table 14 and Table 15 contain the system bus clock specifications, Table 16 contains the AGTL+/AGTL specifications, Table 17 contains the CMOS signal group specifications, Table 18 contains timings for the reset conditions, Table 19 and covers APIC bus timing, and Table 20 covers power on timing.

All processor system bus AC specifications for the AGTL+/AGTL signal group are relative to the rising edge of the BCLK input. All AGTL+/AGTL timings are referenced to V_{REF} for both '0' and '1' logic levels unless otherwise specified.

The timings specified in this section should be used in conjunction with the I/O buffer models provided by Intel. These I/O buffer models, which include package information, are available for the Pentium III processor in the FC-PGA package in Viewlogic* XTK/XNS* model format (formerly known as QUAD format) and IBIS * 3.1 format as the *Pentium III Processor for the PGA370 Socket I/O Buffer Models* (Electronic Format).

AGTL and AGTL+ layout guidelines are also available in the appropriate platform design guide.

Care should be taken to read all notes associated with a particular timing parameter.

2.12.1 I/O Buffer Model

An electronic copy of the I/O Buffer Model for the AGTL+ and CMOS signals is available at Intel's Developer's Website (http://developer.intel.com). The model is for use in single processor designs and assumes the presence of motherboard R_{TT} values as described in Table 12 on page 36.

Table 14. System Bus AC Specifications (SET Clock)[1, 2]

T# Parameter	Min	Nom	Max	Unit	Figure	Notes
System Bus Frequency		100.00 133.33		MHz		4
T1: BCLK Period	10.0 7.5			ns	9	4, 5, 10 4, 5, 11
T2: BCLK Period Stability			±250 ±250	ps		6, 7, 10 6, 7, 11
T3: BCLK High Time	2.5 1.4			ns	9	9, 10 9, 11
T4: BCLK Low Time	2.4 1.4			ns	9	9, 10 9, 11
T5: BCLK Rise Time	0.4		1.6	ns	9	3, 8
T6: BCLK Fall Time	0.4		1.6	ns	9	3, 8

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors at all frequencies.
2. All AC timings for the AGTL+ signals are referenced to the BCLK rising edge at 1.25 V at the processor pin. All AGTL+ signal timings (address bus, data bus, etc.) are referenced at 1.00 V at the processor pins.

3. Not 100% tested. Specified by design characterization as a clock driver requirement.
4. The internal core clock frequency is derived from the processor system bus clock. The system bus clock to core clock ratio is determined during initialization. Individual processors will only operate at their specified system bus frequency, either 100 MHz or 133 MHz, not both.
5. The BCLK period allows a +0.5 ns tolerance for clock driver variation. See the appropriate clock synthesizer/ driver specification for details.
6. Due to the difficulty of accurately measuring clock jitter in a system, it is recommended that a clock driver be used that is designed to meet the period stability specification into a test load of 10 to 20 pF. This should be measured on the **rising edges of adjacent BCLKs crossing 1.25 V at the processor pin**. The jitter present must be accounted for as a component of BCLK timing skew between devices.
7. The clock driver's closed loop jitter bandwidth must be set low to allow any PLL-based device to track the jitter created by the clock driver. The –20 dB attenuation point, as measured into a 10 to 20 pF load, should be less than 500 kHz. This specification may be ensured by design characterization and/or measured with a spectrum analyzer. See the appropriate clock synthesizer/driver specification for details
8. BCLK Rise time is measure between 0.5 V–2.0 V. BCLK fall time is measured between 2.0 V–0.5 V.
9. BCLK high time is measured as the period of time above 2.0 V. BCLK low time is measured as the period of time below 0.5 V.
10. This specification applies to Pentium III processors operating at a system bus frequency of 100 MHz.
11. This specification applies to Pentium III processors operating at a system bus frequency of 133 MHz

Table 15. System Bus Timing Specifications (Differential Clock)[1, 11, 12]

Parameter	133 MHz		100 MHz		Units	Notes
	Min	Max	Min	Max		
Clock Period—Average	7.5	7.7	10.0	10.2	ns	2, 9, 10
Instantaneous Minimum Clock Period	7.30		9.8		ns	2, 9, 10
CLK Differential Rise Time	175	550	175	467	ps	1, 3
CLK Differential Fall Time	175	550	175	467	ps	1, 3
Waveform Symmetry		325		325	ps	4
Differential Cycle to Cycle Jitter		200		200	ps	1, 5
Differential Duty Cycle	45%	55%	45%	55%		1
Rising Edge Ring Back	0.35		0.35		V	1, 6
Falling Edge Ring Back		–0.35		–0.35	V	1, 6
Cross Point at 1V	0.51	0.76	0.51	0.76	V	7
Input High Voltage	0.92	1.45	0.92	1.45	V	8
Input Low Voltage	–0.2	0.35	–0.2	0.35	V	8

NOTES:
1. Measurement taken from differential waveform, defined as BCLK - BCLK#.
2. Period is defined from one rising 0 V-crossing to the next.
3. Measurement taken from differential waveform, voltage range from -0.35 V to +0.35 V.
4. Measurement taken from common mode waveform, measure rise/fall time from 0.41 V to 0.86 V. Rise/fall time matching is defined as "the instantaneous difference between maximum BCLK rise (fall) and minimum BCLK# fall (rise) time, or minimum BCLK rise (fall) and maximum BCLK# fall (rise) time. "This parameter is designed to guard waveform symmetry.
5. Period difference measured around 0 V-crossings; measurement taken from differential waveform.
6. The rising and falling edge ringback voltage specified is the minimum (rising) or them maximum (falling) voltage, the differential waveform can go after passing Vih_diff (rising) or Vil_diff (falling)
7. Measured in absolute voltage, i.e. single-ended measurement. Includes every cross point for both rise and fall of BCLK.
8. Input high or input low voltage range measured in absolute voltage, i.e. single-ended measurement.
9. The internal Core clock frequency is derived from the processor system bus clock. The system bus clock to core clock ratio is determined during initialization. Individual processors will only operate at their specified system bus frequency 133 MHz. Table 16 shows supported ratios for each processor
10. Due to the difficulty of accurately measuring clock jitter in a system, it is recommended that a clock driver be used that is designed to meet the period stability specification into a test load of 10 pF to 20 pF. The jitter must be accounted for as a component of BCLK timing skew between devices.
11. AC parameters are measured at the processor pins.
12. BCLK/BCLK# must rise/fall monotonically between Vil and Vih.

Table 16. System Bus AC Specifications (AGTL+ or AGTL Signal Group)[1, 2, 3, 13]

T# Parameter	Min	Max	Unit	Figure	Notes
T7: AGTL+ Output Valid Delay	0.40	3.25	ns	11	4, 10, 11
T8: AGTL+ Input Setup Time	1.20		ns	12	5, 6, 7, 10
	0.95		ns	12	5, 6, 7, 11, 12
T9: AGTL+ Input Hold Time	1.00		ns	12	8, 10
T10: RESET# Pulse Width	1.00		ms	13	6, 9, 10

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors at all frequencies.
2. These specifications are tested during manufacturing.
3. All timings for the AGTL+ signals are referenced to the BCLK rising edge at 1.25 V at the processor pins (for AGTL, the timings are referenced to the rising edge of BCLK and the falling edge of BCLK# at the processor pins). All AGTL+ signal timings (compatibility signals, etc.) are referenced at 1.00 V (2/3 V_{TT} for AGTL) at the processor pins.
4. Valid delay timings for these signals are specified into 50 Ω to 1.5 V, V_{REF} at 1.0 V ±2% and with 56 Ω on-die R_{TT}. For AGTL platforms, the valid delay timings are specified into 50 Ω to 1.25 V, V_{REF} at 2/3 V_{TT} ±2% and with 56 Ω on-die R_{TT}.
5. A minimum of 3 clocks must be guaranteed between two active-to-inactive transitions of TRDY#.
6. RESET# can be asserted (active) asynchronously, but must be deasserted synchronously. For 2-way MP systems, RESET# should be synchronous.
7. Specification is for a minimum 0.40 V swing from V_{REF} - 200 mV to V_{REF} + 200 mV. This assumes an edge rate of 0.3V/ns.
8. Specification is for a maximum 1.0 V (2/3 V_{TT} for AGTL) swing from V_{TT} - 1V to V_{TT}. This assumes an edge rate of 3V/ns.
9. This should be measured after Vcc_{CORE}, V_{TT}, Vcc_{CMOS}, and BCLK become stable.
10. This specification applies to the Pentium III processor running at 100 MHz system bus frequency.
11. This specification applies to the Pentium III processor running at 133 MHz system bus frequency.
12. BREQ signals at 133 MHz system bus observe a 1.2 ns minimum setup time.
13. For AGTL, V_{REF} is 2/3 V_{TT} ±3%.

Table 17. System Bus AC Specifications (CMOS Signal Group) [1, 2, 3, 4]

T# Parameter	Min	Max	Unit	Figure	Notes
T14: CMOS Input Pulse Width, except PWRGOOD	2		BCLKs	11	Active and Inactive states
T15: PWRGOOD Inactive Pulse Width	10		BCLKs	11, 14	5

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors at all frequencies
2. These specifications are tested during manufacturing.
3. These signals may be driven asynchronously.
4. All CMOS outputs shall be asserted for at least 2 BCLKs.
5. When driven inactive or after $V_{CC_{CORE}}$, V_{TT}, $V_{CC_{CMOS}}$, and BCLK become stable.

Table 18. System Bus AC Specifications (Reset Conditions) [1]

T# Parameter	Min	Max	Unit	Figure	Notes
T16: Reset Configuration Signals (A[14:5]#, BR0#, INIT#) Setup Time	4		BCLKs	13	Before deassertion of RESET#
T17: Reset Configuration Signals (A[14:5]#, BR0#, INIT#) Hold Time	2	20	BCLKs	13	After clock that deasserts RESET#

NOTE: 1. Unless otherwise noted, all specifications in this table apply to all Pentium III processor frequencies.

Table 19. System Bus AC Specifications (APIC Clock and APIC I/O) [1, 2, 3]

T# Parameter	Min	Max	Unit	Figure	Notes
T21: PICCLK Frequency	2.0	33.3	MHz		
T22: PICCLK Period	30.0	500.0	ns	9	
T23: PICCLK High Time	10.5		ns	9	@ > 1.7V
T24: PICCLK Low Time	10.5		ns	9	@ < 0.7V
T25: PICCLK Rise Time	0.25	3.0	ns	9	(0.7V - 1.7V)
T26: PICCLK Fall Time	0.25	3.0	ns	9	(1.7V - 0.7V)
T27: PICD[1:0] Setup Time	5.0		ns	12	4
T28: PICD[1:0] Hold Time	2.5		ns	12	4
T29a: PICD[1:0] Valid Delay (Rising Edge)	1.5	8.7	ns	10, 11	4, 5, 6
T29b: PICD[1:0] Valid Delay (Falling Edge)	1.5	12.0	ns	10, 11	4, 5, 6

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors at all frequencies.
2. These specifications are tested during manufacturing.
3. All AC timings for the APIC I/O signals are referenced to the PICCLK rising edge at 1.25 V at the processor pins. All APIC I/O signal timings are referenced at 0.75 V at the processor pins.
4. Referenced to PICCLK rising edge.
5. For open drain signals, valid delay is synonymous with float delay.
6. Valid delay timings for these signals are specified into 150 Ω load pulled up to 1.5 V.

Table 20. Platform Power-On Timings [2]

T# Parameter	Min	Max	Unit	Figure	Notes
T45: Valid Time Before VTT_PWRGD	1.0		mS	14	1
T46: Valid Time Before PWRGOOD	2.0		mS	14	1
T47: RESET# Inactive to Valid Outputs	1		BCLK	14	1
T48: RESET# Inactive to Drive Signals	4		BCLK	14	1

NOTES:

1. All signals, during their invalid states, must be guarded against spurious levels from effecting the platform during processor power-up sequence.
2. Configuration Input signals include: A[14:5], BR0#, BR1#, INIT#. For timing of these signals, please refer to Table 17 and Figure 13.

Note: For Figure 9 through Figure 15, the following apply:

1. Figure 9 through Figure 15 are to be used in conjunction with Table 14 through Table 20.

2. All AC timings for the AGTL+ signals at the processor pins are referenced to the BCLK rising edge at 1.25 V. All AGTL+ signal timings (address bus, data bus, etc.) are referenced at 1.00 V at the processor pins.

3. All AC timings for the APIC I/O signals at the processor pins are referenced to the PICCLK rising edge at 1.25 V. All APIC I/O signal timings are referenced at 0.75 V at the processor pins.

4. All AC timings for the TAP signals at the processor pins are referenced to the TCK rising edge at 0.75 V. All TAP signal timings (TMS, TDI, etc.) are referenced at 0.75 V at the processor pins.

3.0 Signal Quality Specifications

Signals driven on the processor system bus should meet signal quality specifications to ensure that the components read data properly and to ensure that incoming signals do not affect the long term reliability of the component. Specifications are provided for simulation at the processor pins. Meeting the specifications at the processor pins in Table 21, Table , Table 23, Table , and Table ensures that signal quality effects will not adversely affect processor operation.

3.1 BCLK/BCLK# and PICCLK Signal Quality Specifications and Measurement Guidelines

Table 21 describes the signal quality specifications at the processor pins for the processor system bus clock (BCLK) and APIC clock (PICCLK) signals. Figure 16 describes the signal quality waveform for the system bus clock at the processor pins.

Table 21. BCLK/PICCLK Signal Quality Specifications for Simulation at the Processor Pins [1]

T# Parameter	Min	Nom	Max	Unit	Figure	Notes
V1: BCLK V_{IL}			0.500	V	16	
V1: PICCLK V_{IL}			0.700	V	16	
V2: BCLK V_{IH}	2.000			V	16	
V2 PICCLK V_{IH}	2.000			V	16	
V3: V_{IN} Absolute Voltage Range	−0.58		3.18	V	16	
V4: BCLK Rising Edge Ringback	2.000			V	16	2
V4: PICCLK Rising Edge Ringback	2.000			V	16	2
V5: BCLK Falling Edge Ringback			0.500	V	16	2
V5: PICCLK Falling Edge Ringback			0.700	V	16	2

NOTES:
1. Unless otherwise noted, all specifications in this table apply to all Pentium III processors frequencies.
2. The rising and falling edge ringback voltage specified is the minimum (rising) or maximum (falling) absolute voltage the BCLK/PICCLK signal can dip back to after passing the V_{IH} (rising) or V_{IL} (falling) voltage limits. This specification is an absolute value.

Table 22. BCLK/PICCLK Signal Quality Specifications for Simulation at the Processor Pins in a Differential Clock Platform for AGTL

T# Parameter	Min	Nom	Max	Unit	Figure	Notes
V1: PICCLK V_{IL}			0.40	V	16	
V2 PICCLK V_{IH}	1.60			V	16	
V3: PICCLK Absolute Voltage Range	-0.4		2.4	V	16	
V4: PICCLK Rising Edge Ringback	1.60			V	16	2
V5: PICCLK Falling Edge Ringback			0.40	V	16	2

NOTES:
1. Unless otherwise noted, all specifications in this table apply to Pentium III processors that support the AGTL specification. Refer to the *Intel® Pentium® III Processor Specification Update* for a complete listing on the processors that support the AGTL specification.

2. The rising and falling edge ringback voltage specified is the minimum (rising) or maximum (falling) absolute voltage the BCLK/PICCLK signal can dip back to after passing the V_{IH} (rising) or V_{IL} (falling) voltage limits. This specification is an absolute value.

Figure 16. BCLK, PICCLK Generic Clock Waveform at the Processor Pins
3.2 AGTL+ / AGTL Signal Quality Specifications and Measurement Guidelines

Many scenarios have been simulated to generate a set of AGTL+ layout guidelines which are available in the appropriate platform design guide. Refer to the *Intel® Pentium® II Processor Developer's Manual* (Order Number 243502) for the AGTL+/AGTL buffer specification.

Table 23 provides the AGTL+ signal quality specifications for the processor for use in simulating signal quality at the processor pins.

The Pentium III processor for the PGA370 socket maximum allowable overshoot and undershoot specifications for a given duration of time are detailed in Table 25 through Table 27. Figure 17 shows the AGTL+/AGTL ringback tolerance and Figure 18 shows the overshoot/undershoot waveform.

Table 23. AGTL+ Signal Groups Ringback Tolerance Specifications at the Processor Pins [1, 2, 3]

T# Parameter	Min	Unit	Figure	Notes
α: Overshoot	100	mV	17	4, 8
τ: Minimum Time at High	0.50	ns	17	
ρ: Amplitude of Ringback	±200	mV	17	5, 6, 7, 8
φ: Final Settling Voltage	200	mV	17	8
δ: Duration of Squarewave Ringback	N/A	ns	17	

NOTES:
1. Unless otherwise noted, all specifications in this table apply to all Pentium III processors frequencies.
2. Specifications are for the edge rate of 0.3 - 0.8V/ns. See Figure 17 for the generic waveform.
3. All values specified by design characterization.
4. Please see Table 25 for maximum allowable overshoot.
5. Ringback between V_{REF} + 100 mV and V_{REF} + 200 mV or V_{REF} - 200 mV and V_{REF} - 100 mVs requires the flight time measurements to be adjusted as described in the Intel AGTL+ Specifications (*Intel®Pentium®II Developers Manual*). Ringback below V_{REF} + 100 mV or above V_{REF} - 100 mV is not supported.

6. Intel recommends simulations not exceed a ringback value of V_{REF} ±200 mV to allow margin for other sources of system noise.
7. A negative value for ρ indicates that the amplitude of ringback is above V_{REF}. (i.e., φ = -100 mV specifies the signal cannot ringback below V_{REF} + 100 mV).
8. φ and ρ: are measured relative to V_{REF}. α: is measured relative to V_{REF} + 200 mV.

Figure 17. Low to High AGTL+ Receiver Ringback Tolerance

Note: High to low case is analogous
3.3 AGTL+ Signal Quality Specifications and Measurement Guidelines

3.3.1 Overshoot/Undershoot Guidelines

Overshoot (or undershoot) is the absolute value of the maximum voltage above the nominal high voltage or below Vss. The overshoot guideline limits transitions beyond Vcc or Vss due to the fast signal edge rates. The processor can be damaged by repeated overshoot events on 1.5 V or 2.5 V tolerant buffers if the charge is large enough (i.e., if the overshoot is great enough). Determining the impact of an overshoot/undershoot condition requires knowledge of the magnitude, the pulse direction and the activity factor (AF). Permanent damage to the processor is the likely result of excessive overshoot/undershoot. Violating the overshoot/undershoot guideline will also make satisfying the ringback specification difficult.

When performing simulations to determine impact of overshoot and overshoot, ESD diodes must be properly characterized. ESD protection diodes do not act as voltage clamps and will not provide overshoot or undershoot protection. ESD diodes modeled within Intel I/O Buffer models do not clamp undershoot or overshoot and will yield correct simulation results. If other I/O buffer models are being used to characterize the Pentium III processor performance, care must be taken to ensure that ESD models do not clamp extreme voltage levels. Intel I/O Buffer models also contain I/O capacitance characterization. Therefore, removing the ESD diodes from an I/O Buffer model will impact results and may yield excessive overshoot/undershoot.

3.3.2 Overshoot/Undershoot Magnitude

Magnitude describes the maximum potential difference between a signal and its voltage reference level, V_{SS} (overshoot) and V_{TT} (undershoot). While overshoot can be measured relative to V_{SS} using one probe (probe to signal and GND lead to V_{SS}), undershoot must be measured relative to V_{TT}. This could be accomplished by simultaneously measuring the V_{TT} plane while measuring the signal undershoot. Today's oscilloscopes can easily calculate the true undershoot waveform. The true undershoot waveform can also be obtained with the following oscilloscope data file analysis:

Converted Undershoot Waveform = V_{TT} - Signal_measured

Note: The converted undershoot waveform appears as a positive (overshoot) signal.

Note: Overshoot (rising edge) and undershoot (falling edge) conditions are separate and their impact must be determined independently.

After the true waveform conversion, the undershoot/overshoot specifications shown in Table 25 through Table 27 can be applied to the converted undershoot waveform using the same magnitude and pulse duration specifications used with an overshoot waveform.

Overshoot/undershoot magnitude levels must observe the Absolute Maximum Specifications listed in Table 25 through Table 27. These specifications must not be violated at any time regardless of bus activity or system state. Within these specifications are threshold levels that define different allowed pulse durations. Provided that the magnitude of the overshoot/undershoot is within the Absolute Maximum Specifications (2.18V), the pulse magnitude, duration and activity factor must all be used to determine if the overshoot/undershoot pulse is within specifications.

3.3.3 Overshoot/Undershoot Pulse Duration

Pulse duration describes the total time an overshoot/undershoot event exceeds the overshoot/undershoot reference voltage (Vos_ref = 1.635 V). The total time could encompass several oscillations above the reference voltage. Multiple overshoot/undershoot pulses within a single overshoot/undershoot event may need to be measured to determine the total pulse duration.

Note: Oscillations below the reference voltage cannot be subtracted from the total overshoot/undershoot pulse duration.

Note: Multiple Overshoot/Undershoot events occurring within the same clock cycle must be considered together as one event. Using the worst case Overshoot/Undershoot Magnitude, sum together the individual Pulse Durations to determine the total Overshoot/Undershoot Pulse Duration for that total event.

3.3.4 Activity Factor

Activity Factor (AF) describes the frequency of overshoot (or undershoot) occurrence relative to a clock. Since the highest frequency of assertion of an AGTL+ or a CMOS signal is every other clock, an AF = 1 indicates that the specific overshoot (or undershoot) waveform occurs EVERY OTHER clock cycle. Thus, an AF = 0.01 indicates that the specific overshoot (or undershoot) waveform occurs one time in every 200 clock cycles.

The specifications provided in Table 25 through Table 27 show the Maximum Pulse Duration allowed for a given Overshoot/Undershoot Magnitude at a specific Activity Factor. Each Table entry is independent of all others, meaning that the Pulse Duration reflects the existence of overshoot/undershoot events of that magnitude **only**. A platform with an overshoot/undershoot that

just meets the pulse duration for a specific magnitude where the AF < 1, means that there can be NO other overshoot/undershoot events, even of lesser magnitude (note that if AF = 1, then the event occurs at all times and no other events can occur).

Note: Activity factor for AGTL+ signals is referenced to BCLK frequency.

Note: Activity factor for CMOS signals is referenced to PICCLK frequency.

3.3.5 Reading Overshoot/Undershoot Specification Tables

The overshoot/undershoot specification for the Pentium III processor for the PGA370 socket is not a simple single value. Instead, many factors are needed to determine what the over/undershoot specification is. In addition to the magnitude of the overshoot, the following parameters must also be known: the junction temperature the processor will be operating at, the width of the overshoot (as measured above 1.635 V) and the Activity Factor (AF). To determine the allowed overshoot for a particular overshoot event, the following must be done:

1. Determine the signal group that particular signal falls into. If the signal is an AGTL+ signal operating with a 100 MHz system bus, use Table 25 (100MHz AGTL+ signal group). If the signal is an AGTL+ signal operating with a 133MHz system bus, use Table 26 (133 MHz AGTL+ signal group). If the signal is a CMOS signal, use Table 27 (33 MHz CMOS signal group).

2. Determine the maximum junction temperature (Tj) for the range of processors that the system will support (80°C or 85°C).

3. Determine the Magnitude of the overshoot (relative to Vss)

4. Determine the Activity Factor (how often does this overshoot occur?)

5. From the appropriate Specification table, read off the Maximum Pulse Duration (in ns) allowed.

6. Compare the specified Maximum Pulse Duration to the signal being measured. If the Pulse Duration measured is less than the Pulse Duration shown in the table, then the signal meets the specifications.

The above procedure is similar for undershoots after the undershoot waveform has been converted to look like an overshoot. Undershoot events must be analyzed separately from Overshoot events as they are mutually exclusive.

Below is an example showing how the maximum pulse duration is determined for a given waveform.

Table 24. Example Platform Information

Required Information	Maximum Platform Support	Notes
FSB Signal Group	133 MHz AGTL+	
Max Tj	85 °C	
Overshoot Magnitude	2.13V	Measured Value
Activity Factor (AF)	0.1	Measured overshoot occurs on average every 20 clocks

NOTES:
1. Corresponding Maximum Pulse Duration Specification - 2.4 ns
2. Pulse Duration (measured) - 2.0 ns

Given the above parameters, and using Table 26 (85 °C/AF = 0.1 column) the maximum allowed pulse duration is 2.4 ns. Since the measure pulse duration is 2.0 ns, this particular overshoot event passes the overshoot specifications, although this doesn't guarantee that the combined overshoot/undershoot events meet the specifications.

3.3.6 Determining if a System Meets the Overshoot/Undershoot Specifications

The overshoot/undershoot specifications listed in the following tables specify the allowable overshoot/undershoot for a single overshoot/undershoot event. However most systems will have multiple overshoot and/or undershoot events that each have their own set of parameters (duration, AF and magnitude). While each overshoot on its own may meet the overshoot specification, when you add the total impact of all overshoot events, the system may fail. A guideline to ensure a system passes the overshoot and undershoot specifications is shown below. It is important to meet these guidelines; otherwise, contact your Intel field representative.

1. Insure no signal (CMOS or AGTL+/AGTL) ever exceed the 1.635 V

    OR

2. If only one overshoot/undershoot event magnitude occurs, ensure it meets the over/undershoot specifications in the following tables

    OR

3. If multiple overshoots and/or multiple undershoots occur, measure the worst case pulse duration for each magnitude and compare the results against the AF = 1 specifications. If all of these worst case overshoot or undershoot events meet the specifications (measured time < specifications) in the table (where AF=1), then the system passes.

The following notes apply to Table 25 through Table 27.

NOTES:
1. Overshoot/Undershoot Magnitude = 2.18 V is an Absolute value and should never be exceeded
2. Overshoot is measured relative to V_{SS}.
3. Undershoot is measured relative to V_{TT}
4. Overshoot/Undershoot Pulse Duration is measured relative to 1.635 V.
5. Ringbacks below V_{TT} can not be subtracted from Overshoots/Undershoots
6. Leser Undershoot does not allocate longer or larger Overshoot
7. OEM's are encouraged to follow Intel provided layout guidelines. Consult the layout guidelines provided in the specific platform design guide.
8. All values specified by design characterization

Table 25. 100 MHz AGTL+ / AGTL Signal Group Overshoot/Undershoot Tolerance at Processor Pins[1,2]

Overshoot/ Undershoot Magnitude	Maximum Pulse Duration at Tj = 80 °C (ns)			Maximum Pulse Duration at Tj = 85 °C (ns)		
	AF = 0.01	AF = 0.1	AF = 1	AF = 0.01	AF = 0.1	AF = 1
2.18 V	20	2.53	0.25	18.6	1.86	0.18

2. Measurements taken at the processor socket pins on the solder-side of the motherboard.

Figure 18. Maximum Acceptable AGTL+ Overshoot/Undershoot Waveform
Figure 19. Maximum Acceptable AGTL Overshoot/Undershoot Waveform
3.4 Non-AGTL+ (Non-AGTL) Signal Quality Specifications and Measurement Guidelines

There are three signal quality parameters defined for non-AGTL+ signals: overshoot/undershoot, ringback, and settling limit. All three signal quality parameters are shown in Figure 20 for the non-AGTL+ signal group.

Figure 20. Non-AGTL+ (Non-AGTL) Overshoot/Undershoot, Settling Limit, and Ringback [1]
NOTES:

1. V_{HI} = 1.5 V for all non-AGTL+ signals except for BCLK, PICCLK, and PWRGOOD. V_{HI} = 2.5 V for BCLK, PICCLK, and PWRGOOD. BCLK and PICCLK signal quality is detailed in Section 3.1.

3.4.1 Overshoot/Undershoot Guidelines

Overshoot (or undershoot) is the absolute value of the maximum voltage above the nominal high voltage or below V_{SS}. The overshoot guideline limits transitions beyond V_{CC} or V_{SS} due to the fast signal edge rates (see Figure 20 for non-AGTL+ signals). The processor can be damaged by repeated overshoot events on 1.5 V or 2.5 V tolerant buffers if the charge is large enough (i.e., if the overshoot is great enough). Permanent damage to the processor is the likely result of excessive overshoot/undershoot. Violating the overshoot/undershoot guideline will also make satisfying the ringback specification difficult. *The overshoot/undershoot guideline is 0.3 V* and assumes the absence of diodes on the input. These guidelines should be verified in simulations *without the on-chip ESD protection diodes present* because the diodes will begin clamping the 1.5 V and 2.5 V tolerant signals beginning at approximately 0.7 V above the appropriate supply and 0.7 V below V_{SS}. If signals are not reaching the clamping voltage, this will not be an issue. A system should not rely on the diodes for overshoot/undershoot protection as this will negatively affect the life of the components and make meeting the ringback specification very difficult.

Note: The undershoot guideline limits transitions exactly as described for the ATGL+/AGTL signals. See Figure 18.

3.4.2 Ringback Specification

Ringback refers to the amount of reflection seen after a signal has switched. The ringback specification is the voltage that the signal rings back to after achieving its maximum absolute value. See Figure 20 for an illustration of ringback. Excessive ringback can cause false signal detection or extend the propagation delay. The ringback specification applies to the input pin of each receiving agent. Violations of the signal ringback specification are not allowed under any circumstances for non-AGTL+ (non-AGTL) signals.

Ringback can be simulated with or without the input protection diodes that can be added to the input buffer model. However, signals that reach the clamping voltage should be evaluated further. See Table for the signal ringback specifications for non-AGTL+ signals for simulations at the processor pins.

Table 28. Signal Ringback Specifications for Non-AGTL+ Signal Simulations at the Processor Pins[1]

Input Signal Group	Transition	Maximum Ringback (with Input Diodes Present)	Unit	Figure
Non-AGTL+ Signals [2]	$0 \rightarrow 1$	V_{CMOS_REF} + 0.200	V	20
Non-AGTL+ Signals [2]	$1 \rightarrow 0$	V_{CMOS_REF} - 0.200	V	20
PWRGOOD	$0 \rightarrow 1$	2.00	V	20

NOTES:
1. Unless otherwise noted, all specifications in this table apply to all Pentium III processor frequencies.
2. Non-AGTL+ signals except PWRGOOD.

Table 29. Signal Ringback Specifications for Non-AGTL Signal Simulations at the Processor Pins [1]

Input Signal Group	Transition	Maximum Ringback (with Input Diodes Present)	Unit	Figure
Non-AGTL+ Signals [2]	$0 \rightarrow 1$	V_{CMOS_REF} + 0.200	V	20
Non-AGTL+ Signals [2]	$1 \rightarrow 0$	V_{CMOS_REF} - 0.300	V	20
PWRGOOD	$0 \rightarrow 1$	2.00 [3]	V	20

NOTES:
1. Unless otherwise noted, all specifications in this table apply to all Pentium III processor frequencies.
2. Non-AGTL signals except PWRGOOD.
3. For Coppermine-T with differential clocking, this signal is 1.8 V tolerant.

3.4.3 Settling Limit Guideline

Settling limit defines the maximum amount of ringing at the receiving pin that a signal must reach before its next transition. The amount allowed is 10% of the total signal swing (V_{HI}–V_{LO}) above and below its final value. A signal should be within the settling limits of its final value, when either in its high state or low state, before it transitions again.

Signals that are not within their settling limit before transitioning are at risk of unwanted oscillations which could jeopardize signal integrity. Simulations to verify settling limit may be done either with or without the input protection diodes present. Violation of the settling limit guideline is acceptable if simulations of 5 to 10 successive transitions do not show the amplitude of the ringing increasing in the subsequent transitions.

4.0 Thermal Specifications and Design Considerations

This chapter provides needed data for designing a thermal solution. However, for the correct thermal measuring processes, refer to AP-905, *Intel® Pentium® III Processor Thermal Design Guidelines* (Document Number 245087). The Pentium III processor uses flip chip pin grid array packaging technology and has a **junction** ($T_{junction}$) or **case** temperature (T_{case}) specified.

4.1 Thermal Specifications

Table 30 provides the thermal design power dissipation and maximum temperatures for the Pentium III processor for the PGA370 socket. Systems should design for the highest possible processor power, even if a processor with a lower thermal dissipation is planned. A thermal solution should be designed to ensure the junction temperature never exceeds these specifications.

Table 30. Intel® Pentium® III Processor Thermal Design Power for the FC-PGA Package[1]

Processor	Processor Core Frequency (MHz)	System Bus Frequency (MHz)	Processor Thermal Design Power [2,3] up to CPUID 0686h (W)	Processor Thermal Design Power [2,3] CPUID 068Ah (W)	Power Density[5] for CPUID 068Ah (W/cm²)	Maximum $T_{JUNCTION}$[10] (°C)		$T_{JUNCTION}$ Offset for Latest Stepping [4,6] (°C)
500E	500	100	13.2	N/A	N/A	85		1.9

800EB	800	133	20.8	24.5	38.2	80		3.2
850	850	100	22.5	25.7	40.0	80		3.4
866	866	133	22.9	26.1	40.7	80		3.4
900	900	100	23.2	26.7	41.6	77		3.5
933	933	133	24.5	27.5	42.8	77		3.6
1 GHz	1000	100	N/A	29.0	45.2	75[8]		3.8
1B GHz	1000	133	26.1	29.0	45.2	70[9]	75[8]	3.8
1B GHz[7]	1000	133	29.6	N/A	N/A	70		3.9
1.10 GHz	1100	100	N/A	33.0	51.4	77		4.4

NOTES:
1. These values are specified at nominal $V_{CC_{CORE}}$ for the processor pins.

2. Thermal Design Power (TDP) represents the maximum amount of power the thermal solution is required to dissipate. The thermal solution should be designed to dissipate the TDP power without exceeding the maximum Tjunction specification.

3. TDP does not represent the power delivery and voltage regulation requirements for the processor. Refer to Table 6 for voltage regulation and electrical specifications.

4. $T_{junctionoffset}$ is the worst-case difference between the thermal reading from the on-die thermal diode and the hottest location on the processor's core.

5. Power density is the maximum power the processor die can dissipate (i.e., processor power) divided by the die area over which the power is generated. Power for these processors is generated from the core area shown in Figure 21.

6. TJUNCTION offset values do not include any thermal diode kit measurement error. Diode kit measurement error must be added to the TJUNCTION offset value from the table, as outlined in the *Intel® Pentium® III processor Thermal Metrology for CPUID-068h Family Processors* (Order Number: 245301). Intel has characterized the use of the Analog Devices AD1021 diode measurement kit and found its measurement error to be 1 °C.

7. This specification only applies to 1B GHz S-Spec #: SL4WM. This part has a VID request of 1.70 V, however the processor should be supplied 1.76 V at the PGA Vcc pins by the VRM (Voltage Regulator Module) or by the voltage regulator circuit.

8. This specification applies to processors with CPUID 068AH. 1B GHz exists in both FC-PGA and FC-PGA2 packages.

9. This specification applies to processors with CPUID 0686H.

10. Tjunction minimum specification is 0 °C.

Table 31 provides the thermal design power dissipation and maximum temperatures for the Pentium III processor for the FC-PGA2 package. Systems should design for the highest possible processor power, even if a processor with a lower thermal dissipation is planned. A thermal solution should be designed to ensure the case temperature never exceeds these specifications.

Table 31. Intel® Pentium® III Processor for the FC-PGA2 Package Thermal Design Power [1]

Processor	Processor Core Frequency (MHz)	System Bus Frequency (MHz)	Processor Thermal Design Power [2,3] CPUID 068Ah (W)	Maximum T_{case} [4] (°C)	Additional Notes
866	866	133	29.5	70	5
933	933	133	31.5	72	5
1B GHz	1000	133	33.9	69	5
1.13 GHz	1133	133	37.5	72	

NOTES:
1. These values are specified at nominal Vcc_{CORE} for the processor pins.
2. Thermal Design Power (TDP) represents the maximum amount of power the thermal solution is required to dissipate. The thermal solution should be designed to dissipate the TDP power without exceeding the maximum Tcase specification.
3. TDP does not represent the power delivery and voltage regulation requirements for the processor. Refer to Table 7 for voltage regulation and electrical specifications.
4. $T_{CaseOffset}$ is the worst-case difference between the maximum case temperature and the thermal diode temperature on the processor's core. For more information please refer to the document, *Intel® Pentium® III Processor in the FC-PGA2 Package Thermal Design Guide.*
5. This processor exists in both FC-PGA and FC-PGA2 packages.

4.2 Processor Die Area

Figure 21 is a block diagram of the Pentium III processor die layout and Table 32 contains Pentium III processor die layout measurements. The layout differentiates the processor core from the cache die area. In effect, the thermal design power identified in Table 30 is dissipated entirely from the processor core area. Thermal solution designs should compensate for this smaller heat flux area and not assume that the power is uniformly distributed across the entire die area.

Figure 21. Processor Functional Die Layout for FC-PGA
Table 32. Processor Functional Die Layout for FC-PGA

CPUID	A: Die Area (cm^2)	B: Core Area (cm^2)	C: Cache Area (cm^2)
0683H	1.046	0.726	0.320
0686H	0.900	0.642	0.258
068AH	0.947	0.642	0.305

4.3   Thermal Diode

The Pentium III processor for the PGA370 socket incorporates an on-die diode that may be used to monitor the die temperature (junction temperature). A thermal sensor located on the motherboard, or a stand-alone measurement kit, may monitor the die temperature of the processor for thermal management or instrumentation purposes. Table 33 and Table 34 provide the diode parameter and interface specifications. For more information please refer to the document, *Intel® Pentium® III Processor in the FC-PGA2 Package Thermal Design Guide.*

Note: The reading of the thermal sensor connected to the thermal diode will not necessarily reflect the temperature of the hottest location on the die. This is due to inaccuracies in the thermal sensor, on-die temperature gradients between the location of the thermal diode and the hottest location on the die at a given point in time, and time based variations in the die temperature measurement. Time based variations can occur when the sampling rate of the thermal diode (by the thermal sensor) is slower than the rate at which the $T_{junction}$ temperature can change.

Table 33. Thermal Diode Parameters[1]

Symbol	Parameter	Min	Typ	Max	Unit	Notes
I_{fw}	Forward Bias Current	5		300	µA	1
n	Diode Ideality Factor	1.0057	1.0080	1.0125		2, 3, 4

NOTES:
1. Intel does not support or recommend operation of the thermal diode under reverse bias.
2. Characterized at 100 ° C with a forward bias current of 5 µA–300 µA.
3. The ideality factor, n, represents the deviation from ideal diode behavior as exemplified by the diode equation:
   $I_{fw}=Is(e^{((Vd*q)/(nkT))} - 1)$, where Is = saturation current, q = electronic charge, Vd = voltage across the diode, k = Boltzmann Constant, and T = absolute temperature (Kelvin).
4. Not 100% tested. Specified by design characterization.

Table 34. Thermal Diode Interface

Pin Name	PGA370 Socket pin #	Pin Description
THERMDP	AL31	diode anode (p_junction)
THERMDN	AL29	diode cathode (n_junction)

5.0   Mechanical Specifications

The Pentium III processor uses a FC-PGA and FC-PGA2 package technology. Mechanical specifications for the processor are given in this section. FC-PGA2 contains an Integrated Heat Spreader (IHS) to spread out the heat generated from the die. See Section 1.1.1 for a complete terminology listing.

The processor utilizes a PGA370 socket for installation into the motherboard. Details on the socket are available in the *370-Pin Socket (PGA370) Design Guidelines*.

Note: For Figure 23 and Figure 24 the following apply:

1. Unless otherwise specified, the following drawings are dimensioned in inches.

2. All dimensions provided with tolerances are guaranteed to be met for all normal production product.

3. Figures and drawings labeled as "Reference Dimensions" are provided for informational purposes only. Reference dimensions are extracted from the mechanical design database and are nominal dimensions with no tolerance information applied. Reference dimensions are NOT checked as part of the processor manufacturing. Unless noted as such, dimensions in parentheses without tolerances are reference dimensions.

4. Drawings are not to scale.

The following figure with package dimensions is provided to aid in the design of heatsink and clip solutions as well as demonstrate where pin-side capacitors will be located on the processor. Table 35 includes the measurements for these dimensions in both inches and millimeters.

Figure 22. FC-PGA and FC-PGA2 Package Types

FC-PGA2   FC-PGA
5.1   FC-PGA Mechanical Specifications

The following figure with package dimensions is provided to aid in the design of heatsink and clip solutions as well as demonstrate where pin-side capacitors will be located on the processor. Table 35 includes the measurements for these dimensions in both inches and millimeters.

Figure 23. Package Dimensions
Table 35. Intel® Pentium® III Processor Package Dimensions

Symbol	Millimeters			Inches		
	Minimum	Maximum	Notes	Minimum	Maximum	Notes
A1	0.787	0.889		0.031d	0.035	
A2	1.000	1.200		0.039	0.047	
B1	11.226	11.329		0.442	0.446	
B2	9.296	9.398		0.366	0.370	
C1	23.495 max			0.925 max		
C2	21.590 max			0.850 max		
D	49.428	49.632		1.946	1.954	
D1	45.466	45.974		1.790	1.810	
G1	0.000	17.780		0	0.700	
G2	0.000	17.780		0	0.700	
G3	0.000	0.889		0	0.035	
H	2.540		Nominal	0.100		Nominal
L	3.048	3.302		0.120	0.130	
ΦP	0.431	0.483	Pin Diameter	0.017	0.019	
Pin TP	0.508 Diametric True Position (Pin-to-Pin)			0.020 Diametric True Position (Pin-to-Pin)		

NOTE: Capacitors will be placed on the pin-side of the FC-PGA package in the area defined by G1, G2, and G3. This area is a keepout zone for motherboard designers.

The bare processor die has mechanical load limits that should not be exceeded during heat sink assembly, mechanical stress testing, or standard drop and shipping conditions. The heatsink attach solution must not induce permanent stress into the processor substrate with the exception of a uniform load to maintain the heatsink to the processor thermal interface. The package dynamic and static loading parameters are listed in Table 36.

For Table 36, the following apply:

1. It is not recommended to use any portion of the processor substrate as a mechanical reference or load bearing surface for thermal solutions.

2. Parameters assume uniformly applied loads.

Table 36. Processor Die Loading Parameters for FC-PGA

Parameter	Dynamic (max)[1]	Static (max)[2]	Unit	Added Notes
Silicon Die Surface	200	50	lbf	3
Silicon Die Edge	100	12	lbf	3

NOTES:
1. This specification applies to a uniform and a non-uniform load.
2. This is the maximum static force that can be applied by the heatsink and clip to maintain the heatsink and processor interface.
3. Please see socket manufacturer's force loading specification also to ensure compliance.

5.1.1 FC-PGA2 Mechanical Specifications

The following figure is provided to aid in the design of heatsink and clip solutions. Also, it is used to demonstrate where pin-side capacitors will be located on the processor. Table 31 includes the measurements for these dimensions in both inches and millimeters.

Figure 24. Package Dimensions for FC-PGA2
Table 37. Package Dimensions for Intel® Pentium® III Processor FC-PGA2 Package

Symbol	Millimeters			Inches		
	Minimum	Maximum	Notes	Minimum	Maximum	Notes
A1	2.266	2.690		0.089	0.106	
A2	0.980	1.180		0.038	0.047	
B1	30.800	31.200		1.212	1.229	
B2	30.800	31.200		1.212	1.229

D	49.428	49.632		1.946	1.954	
D1	45.466	45.974		1.790	1.810	
G1	0.000	17.780		0.000	0.700	
G2	0.000	17.780		0.000	0.700	
G3	0.000	0.889		0.000	0.035	
H	2.540		Nominal	0.100		Nominal
L	3.048	3.302		0.120	0.130	
ΦP	0.431	0.483		0.017	0.019	

Table 37. Package Dimensions for Intel® Pentium® III Processor FC-PGA2 Package

Symbol	Millimeters			Inches		
	Minimum	Maximum	Notes	Minimum	Maximum	Notes
Pin TP	0.508 Diametric True Position (Pin-to-Pin)			0.020 Diametric True Position (Pin-to-Pin)		

NOTE: Capacitors will be placed on the pin-side of the FC-PGA package in the area defined by G1, G2, and G3. This area is a keepout zone for motherboard designers.

For Table 38, the following apply:

1. It is not recommended to use any portion of the processor substrate as a mechanical reference or load bearing surface for thermal solutions.

2. Parameters assume uniformly applied loads

Table 38. Processor Case Loading Parameters for FC-PGA2

Parameter	Transient (max)[1, 4]	Dynamic (max)[2, 4]	Static (max)[3, 4]	Unit
IHS Surface	200	200	100	lbf
IHS Edge	125	N/A	N/A	lbf
IHS Corner	75	N/A	N/A	lbf

NOTES:
1. Transient loading refers to a one time short duration loading, such as during heatsink installation.
2. Dynamic loading refers to a shock load.
3. This is the maximum static force that can be applied by the heatsink and clip to maintain the heatsink and processor interface.
4. Please see socket manufacturer's force loading specification also to ensure compliance. Maximum static loading listed here does not account for the maximum reaction forces on the socket tabs or pins. Designs must ensure that the socket can withstand this force.

Figure 25. FC-PGA2 Flatness Specification

Note: Flatness specifications in millimeters
5.2   Processor Markings

The following figure exemplifies the processor top-side markings and it is provided to aid in the identification of an Pentium III processor for the PGA370 socket. Table 35 and Table 37 list the measurements for the package dimensions.

5.3 Recommended Mechanical Keep-Out Zones

Figure 29. Volumetric Keep-Out for FC-PGA and FC-PGA2 [1,2]
NOTES:
1. This drawing applies to FC-PGA2 package. The only differences from the FC-PGA package Keep-Out drawing are as follows: height 2.160" was changed from 2.100" and height 1.118" was changed from 1.058".
2. Refer to the Pentium III Thermal/Mechanical Solution Functional Guidelines (see section 1.2 for reference order number) for the latest information.

Figure 30. Component Keep-Out
5.4   Processor Signal Listing

Table 39 and Table 40 provide the processor pin definitions. The signal locations on the PGA370 socket are to be used for signal routing, simulation, and component placement on the baseboard. Figure 31 provides a pin-side view of the Pentium III processor pinout.

**NOTES: See next page for notes.**

NOTES:

1. These pins are required for backwards compatibility with other Intel processors. They are not used by the Pentium III processor. Refer to the appropriate platform design guide and Section 7.1 for implementation details.

2. RESET# signal must be connected to pins AH4 and X4 for backwards compatibility. Refer to the appropriate platform design guide and Section 7.1 for implementation details. If backwards compatibility is not required, then RESET2# (X4) should be connected to GND.

3. $VCC_{1.5}$V must be supplied by the same voltage source supplying the V_{TT} pins.

4. These V_{TT} pins must be left unconnected (N/C) for backwards compatibility with Celeron processors (CPUID 066xh). For designs which do not support the Celeron processors (CPUID 066xh), and for compatibility with future processors, these V_{TT} pins should be connected to the V_{TT} plane. Refer to the appropriate platform design guide and Section 7.1 for implementation details. For dual processor designs, these pins must be connected to V_{TT}.

5. This pin is required for backwards compatibility. If backwards compatibility is not required, this pin may be left connected to $V_{CC_{CORE}}$. Refer to the appropriate platform design guide for implementation details.

6. Previously, PGA370 designs defined this pin as a GND. It is now reserved and must be left unconnected (N/C).

7. Previously, PGA370 socket designs defined this pin as a GND. It is now CLKREF.

8. For Uniprocessor designs, this pin is not used and it is defined as RESERVED. Refer to the *Pentium® III processor Specification Update* for a complete listing of processors that support DP operation.

9. Future low voltage AGTL PGA370 designs will redefine this pin as V_{TT}. Refer to the appropriate platform design guide for connectivity and to the *Pentium® III processor Specification Update* for a complete listing of processors that support the new pinout definition.

10. Future low voltage AGTL PGA370 designs define these pins as GND. Refer to the appropriate platform design guide for connectivity and to the *Pentium® III processor Specification Update* for a complete listing of processors that support the new pinout definition.

11. Future low voltage AGTL PGA370 designs define this pin as RESERVED and must be left unconnected. Refer to the appropriate platform design guide for connectivity.

12. Future low voltage AGTL PGA370 designs will redefine these pins. Refer to the appropriate platform design guide for connectivity and to the *Pentium® III processor Specification Update* for a complete listing of processors that support the new pinout definition.

13. On AGTL and differential clock platforms, this pin is defined as BCLK#.

6.0   Boxed Processor Specifications

The Pentium III processor for the PGA370 socket is also offered as an Intel boxed processor. Intel boxed processors are intended for system integrators who build systems from motherboards and standard components. The boxed Pentium III processor for the PGA370 socket will be supplied with an unattached fan heatsink. This section documents motherboard and system requirements for the fan heatsink that will be supplied with the boxed Pentium III processor. This section is particularly important for OEMs that manufacture motherboards for system integrators. Unless otherwise noted, all figures in this section are dimensioned in inches.

Note: Drawings in this section reflect only the specifications on the Intel boxed processor product. These dimensions should not be used as a generic keep-out zone for all heatsinks. It is the system designer's responsibility to consider their proprietary solution when designing to the required keep-out zone on their system platform and chassis. Refer to the *Intel® Pentium® III Processor Thermal/Mechanical Functional Specifications* for further guidance. Contact your local Intel Sales Representative for this document.

Figure 32. Conceptual Boxed Intel® Pentium® III Processor for the PGA370 Socket
6.1   Mechanical Specifications for the Boxed Intel® Pentium® III Processor

6.1.1   Boxed Processor Thermal Cooling Solution Dimensions

This section documents the mechanical specifications of the boxed Pentium III processor fan heatsink in the FC-PGA package. The boxed processor in the FC-PGA package ships with an un-attached fan heatsink. Figure 32 shows a mechanical representation of the boxed Pentium III processor for the PGA370 socket in the Flip Chip Pin Grid Array (FC-PGA) package.

Section 5.3 of this document also shows the recommended mechanical keepout zones for the boxed processor fan heatsink assembly. Figure 30 and Figure 31 show the **required** keepout dimensions for the boxed processor thermal solution. The cooling fin orientation on the heatsink relative to the PGA-370 socket is subject to change. Contact your local Intel Sales Representative for documentation specific to the boxed fan heatsink orientation relative to the PGA-370 socket. Also, contact your Intel representative for specific fan heatsink dimensions.

The fan heatsink is designed to allow visibility of the FC-PGA processor markings located on top of the package. The FC-PGA processor markings are visible after installation of the fan heatsink due to notched sides of the heatsink base (see Figure 34). The boxed processor fan heatsink is also asymmetrical in that the mechanical step feature (see Figure 33) must sit over the socket's cam. The step allows the heatsink to securely interface with the processor in order to meet thermal requirements.

Note: The heatsink airflow keepout zones found in Figure 35 refer specifically to the boxed processor's active fan heatsink. This does not reflect the worst-case dimensions that may exist with other third party passive or active fan heatsinks.

The Pentium III processor is manufactured in two different packages: FC-PGA and FC-PGA2. For specifications on these two packages please see Section 5.0 of this document. Not all frequencies of Pentium III processors are offered in both packages. The thermal solutions for these two packages are incompatible. Therefore, the thermal solution shipped with each boxed Pentium III processor should only be used with the accompanied processor.
Figure 33. Dimensions of Mechanical Step Feature in Heatsink Base
6.1.2   Boxed Processor Heatsink Weight

The boxed processor thermal cooling solution will not weigh more than 180 grams.

Figure 34. Dimensions of Notches in Heatsink Base

6.1.3   Boxed Processor Thermal Cooling Solution Clip

The boxed processor thermal solution requires installation by a system integrator to secure the thermal cooling solution to the processor after it is installed in the 370-pin socket ZIF socket. Motherboards designed for use by system integrators should take care to consider the implications of clip installation and potential scraping of the motherboard PCB underneath the 370-pin socket attach tabs. Motherboard components should not be placed too close to the 370-pin socket attach tabs in a way that interferes with the installation of the boxed processor thermal cooling solution (see Section 5.3 for specification).

6.2   Thermal Specifications

This section describes the cooling requirements of the thermal cooling solution utilized by the boxed processor.

6.2.1   Boxed Processor Cooling Requirements

The boxed processor is directly cooled with a fan heatsink. However, meeting the processor's temperature specification is also a function of the thermal design of the entire system, and ultimately the responsibility of the system integrator. The processor temperature specification is found in Section 4.0 of this document. The boxed processor fan heatsink is able to keep the processor core within the specifications (see Table 33 and Table 34) in chassis that provide good thermal management.

intel®

For the boxed processor fan heatsink to operate properly, it is critical that the airflow provided to the fan heatsink is unimpeded. Airflow of the fan heatsink is into the center and out of the sides of the fan heatsink. Airspace is required around the fan to ensure that the airflow through the fan heatsink is not blocked. Blocking the airflow to the fan heatsink reduces the cooling efficiency and decreases fan life. Figure 35 illustrates an acceptable airspace clearance for the fan heatsink. It is also recommended that the air temperature entering the fan be kept below 45 ^{o} C. Meeting the processor's temperature specification is the responsibility of the system integrator. The processor temperature specification is found in Section 4.0 of this document.

Figure 35. Thermal Airspace Requirement for all Boxed Intel® Pentium® III Processor Fan Heatsinks in the PGA370 Socket
6.3 Electrical Requirements for the Boxed Intel® Pentium® III Processor

6.3.1 Fan Heatsink Power Supply

The boxed processor's fan heatsink requires a +12 V power supply. A fan power cable is attached to the fan and will draw power from a power header on the motherboard. The power cable connector and pinout are shown in Figure 36. Motherboards must provide a matched power header to support the boxed processor. Table 41 contains specifications for the input and output signals at the fan heatsink connector. The fan heatsink outputs a SENSE (open-collector output) signal that pulses at a rate of two pulses per fan revolution. A motherboard pull-up resistor provides VOH to match the motherboard-mounted fan speed monitor requirements, if applicable. Use of the SENSE signal is optional. If the SENSE signal is not used, pin 3 of the connector should be tied to GND.

The power header on the baseboard must be positioned to allow the fan heatsink power cable to reach it. The power header identification and location should be documented in the motherboard documentation or on the motherboard. Figure 37 shows the recommended location of the fan power connector relative to the PGA370 socket. The motherboard power header should be positioned within 4.00 inches (lateral) from the center of the PGA370 socket.

**Figure 36. Boxed Processor Fan Heatsink Power Cable Connector Description**

Pin	Signal	
1	GND	Straight square pin, 3-pin terminal housing with polarizing ribs and friction locking ramp.
2	+12V	0.100" pin pitch, 0.025" square pin width.
3	SENSE	Waldom/Molex P/N 22-01-3037 or equivalent.

Match with straight pin, friction lock header on motherboard Waldom/Molex P/N 22-23-2031, AMP P/N 640456-3, or equivalent.

Table 41. Fan Heatsink Power and Signal Specifications

Description	Min	Typ	Max
+12 V: 12 volt fan power supply	10.8 V	12 V	13.2 V
IC: Fan current draw			100 mA
SENSE: SENSE frequency (motherboard should pull this pin up to appropriate V_{CC} with resistor)		2 pulses per fan revolution

7.0 Processor Signal Description

This section provides an alphabetical listing of all the Pentium III processor signals. The tables at the end of this section summarize the signals by direction: output, input, and I/O.

7.1 Alphabetical Signals Reference

Table 42. Signal Description (Sheet 1 of 8)

Name	Type	Description
A[35:3]#	I/O	The A[35:3]# (Address) signals define a 2^{36}-byte physical memory address space. When ADS# is active, these pins transmit the address of a transaction; when ADS# is inactive, these pins transmit transaction type information. These signals must connect the appropriate pins of all agents on the processor system bus. The A[35:24]# signals are parity-protected by the AP1# parity signal, and the A[23:3]# signals are parity-protected by the AP0# parity signal. On the active-to-inactive transition of RESET#, the processors sample the A[35:3]# pins to determine their power-on configuration. See the *Intel® Pentium® II Processor Developer's Manual* for details.
A20M#	I	If the A20M# (Address-20 Mask) input signal is asserted, the processor masks physical address bit 20 (A20#) before looking up a line in any internal cache and before driving a read/write transaction on the bus. Asserting A20M# emulates the 8086 processor's address wrap-around at the 1 MB boundary. Assertion of A20M# is only supported in real mode. A20M# is an asynchronous signal. However, to ensure recognition of this signal following an I/O write instruction, it must be valid along with the TRDY# assertion of the corresponding I/O Write bus transaction.
ADS#	I/O	The ADS# (Address Strobe) signal is asserted to indicate the validity of the transaction address on the A[35:3]# pins. All bus agents observe the ADS# activation to begin parity checking, protocol checking, address decode, internal snoop, or deferred reply ID match operations associated with the new transaction. This signal must connect the appropriate pins on all processor system bus agents.
AERR#	I/O	The AERR# (Address Parity Error) signal is observed and driven by all processor system bus agents, and if used, must connect the appropriate pins on all processor system bus agents. AERR# observation is optionally enabled during power-on configuration; if enabled, a valid assertion of AERR# aborts the current transaction. If AERR# observation is disabled during power-on configuration, a central agent may handle an assertion of AERR# as appropriate to the error handling architecture of the system.
AP[1:0]#	I/O	The AP[1:0]# (Address Parity) signals are driven by the request initiator along with ADS#, A[35:3]#, REQ[4:0]#, and RP#. AP1# covers A[35:24]#, and AP0# covers A[23:3]#. A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. This allows parity to be high when all the covered signals are high. AP[1:0]# should connect the appropriate pins of all processor system bus agents.
BCLK/BCLK#	I	The BCLK (Bus Clock) signal determines the bus frequency. All processor system bus agents must receive this signal to drive their outputs and latch their inputs on the BCLK rising edge. All external timing parameters are specified with respect to the BCLK signal.

Table 42. Signal Description (Sheet 2 of 8)

Name	Type	Description
BERR#	I/O	The BERR# (Bus Error) signal is asserted to indicate an unrecoverable error without a bus protocol violation. It may be driven by all processor system bus agents, and must connect the appropriate pins of all such agents, if used. However, Pentium III processors do not observe assertions of the BERR# signal. BERR# assertion conditions are configurable at a system level. Assertion options are defined by the following options: • Enabled or disabled. • Asserted optionally for internal errors along with IERR#. • Asserted optionally by the request initiator of a bus transaction after it observes an error. • Asserted by any bus agent when it observes an error in a bus transaction.
BINIT#	I/O	The BINIT# (Bus Initialization) signal may be observed and driven by all processor system bus agents, and if used must connect the appropriate pins of all such agents. If the BINIT# driver is enabled during power on configuration, BINIT# is asserted to signal any bus condition that prevents reliable future information. If BINIT# observation is enabled during power-on configuration, and BINIT# is sampled asserted, all bus state machines are reset and any data which was in transit is lost. All agents reset their rotating ID for bus arbitration to the state after Reset, and internal count information is lost. The L1 and L2 caches are not affected. If BINIT# observation is disabled during power-on configuration, a central agent may handle an assertion of BINIT# as appropriate to the error handling architecture of the system.
BNR#	I/O	The BNR# (Block Next Request) signal is used to assert a bus stall by any bus agent who is unable to accept new bus transactions. During a bus stall, the current bus owner cannot issue any new transactions. Since multiple agents might need to request a bus stall at the same time, BNR# is a wire-OR signal which must connect the appropriate pins of all processor system bus agents. In order to avoid wire-OR glitches associated with simultaneous edge transitions driven by multiple drivers, BNR# is activated on specific clock edges and sampled on specific clock edges.
BP[3:2]#	I/O	The BP[3:2]# (Breakpoint) signals are outputs from the processor that indicate the status of breakpoints.
BPM[1:0]#	I/O	The BPM[1:0]# (Breakpoint Monitor) signals are breakpoint and performance monitor signals. They are outputs from the processor which indicate the status of breakpoints and programmable counters used for monitoring processor performance.
BPRI#	I	The BPRI# (Bus Priority Request) signal is used to arbitrate for ownership of the processor system bus. It must connect the appropriate pins of all processor system bus agents. Observing BPRI# active (as asserted by the priority agent) causes all other agents to stop issuing new requests, unless such requests are part of an ongoing locked operation. The priority agent keeps BPRI# asserted until all of its requests are completed, then releases the bus by deasserting BPRI#.

Table 42. Signal Description (Sheet 3 of 8)

Name	Type	Description
BR0# BR1#	I/O I	The BR0# and BR1# (Bus Request) pins drive the BREQ[1:0]# signals in the system. The BREQ[1:0]# signals are interconnected in a rotating manner to individual processor pins. The table below gives the rotating interconnect between the processor and bus signals. BR0# (I/O) and BR1# Signals Rotating Interconnect | Bus Signal	Agent 0 Pins	Agent 1 Pins
BREQ0#	BR0#	BR1#
BREQ1#	BR1#	BR0# | During power-up configuration, the central agent must assert the BR0# bus signal. All symmetric agents sample their BR[1:0]# pins on active-to-inactive transition of RESET#. The pin on which the agent samples an active level determines its symmetric agent ID. All agents then configure their pins to match the appropriate bus signal protocol, as shown below. **BR[1:0]# Signal Agent IDs** | Pin Sampled Active in RESET#	Agent ID
---	---
BR0#	0
BR1#	3	
BSEL[1:0]	I/O	These signals are used to select the system bus frequency. A BSEL[1:0] = "01" selects a 100 MHz system bus frequency and a BSEL[1:0] = "11" selects a 133 MHz system bus frequency. The frequency is determined by the processor(s), chipset, and frequency synthesizer capabilities. All system bus agents must operate at the same frequency. The Pentium III processor for the PGA370 socket operates at 100 MHz and 133 MHz system bus frequencies. Individual processors will only operate at their specified front side bus (FSB) frequency. Either 100 MHz or 133 MHz, not both. On motherboards which support operation at either 66 MHz or 100 MHz, a BSEL[1:0] = "x0" will select a 66 Mhz system bus frequency. 66 MHz operation is not support by the Pentium III processor for the PGA370 socket; therefore, BSEL0 is ignored. These signals must be pulled up to 2.5 V or 3.3V with 1 KΩ resistors and provided as a frequency selection signal to the clock driver/synthesizer. If the system motherboard is not capable of operating at 133 MHz, it should ground the BSEL1 signal and generate a 100 MHz system bus frequency. See Section 2.8.2 for implementation examples.
CLKREF	I	The CLKREF input is a filtered 1.25 V supply voltage for the processor PLL. A voltage divider and decoupling solution is provided by the motherboard. See the design guide for implementation details.

Table 42. Signal Description (Sheet 4 of 8)

Name	Type	Description
CPUPRES#	O	The CPUPRES# signal is defined to allow a system design to detect the presence of a terminator device or processor in a PGA370 socket. Combined with the VID combination of VID[3:0]= 1111 (see Section 2.6), a system can determine if a socket is occupied, and whether a processor core is present. See the table below for states and values for determining the presence of a device. PGA370 Socket Occupation Truth Table _(see table below)_
D[63:0]#	I/O	The D[63:0]# (Data) signals are the data signals. These signals provide a 64-bit data path between the processor system bus agents, and must connect the appropriate pins on all such agents. The data driver asserts DRDY# to indicate a valid data transfer.
DBSY#	I/O	The DBSY# (Data Bus Busy) signal is asserted by the agent responsible for driving data on the processor system bus to indicate that the data bus is in use. The data bus is released after DBSY# is deasserted. This signal must connect the appropriate pins on all processor system bus agents.
DEFER#	I	The DEFER# signal is asserted by an agent to indicate that a transaction cannot be guaranteed in-order completion. Assertion of DEFER# is normally the responsibility of the addressed memory or I/O agent. This signal must connect the appropriate pins of all processor system bus agents.
DEP[7:0]#	I/O	The DEP[7:0]# (Data Bus ECC Protection) signals provide optional ECC protection for the data bus. They are driven by the agent responsible for driving D[63:0]#, and must connect the appropriate pins of all processor system bus agents which use them. The DEP[7:0]# signals are enabled or disabled for ECC protection during power on configuration.
DRDY#	I/O	The DRDY# (Data Ready) signal is asserted by the data driver on each data transfer, indicating valid data on the data bus. In a multi-cycle data transfer, DRDY# may be deasserted to insert idle clocks. This signal must connect the appropriate pins of all processor system bus agents.
EDGCTRL	O	The EDGCTRL input adjusts the edge rate of AGTL+ output buffers for previous processors and should be pulled up to $V_{CC_{CORE}}$ with a 51 Ω ±5% resistor. See the platform design guide for implementation details. This signal is not used by the Pentium III processor.
FERR#	O	The FERR# (Floating-point Error) signal is asserted when the processor detects an unmasked floating-point error. FERR# is similar to the ERROR# signal on the Intel387™ coprocessor, and is included for compatibility with systems using MS-DOS*-type floating-point error reporting.

PGA370 Socket Occupation Truth Table

Signal	Value	Status
CPUPRES# VID[3:0]	0 Anything other than '1111'	Processor core installed in the PGA370 socket.
CPUPRES# VID[3:0]	0 1111	Terminator device installed in the PGA370 socket (i.e., no core present).
CPUPRES# VID[3:0]	1 Any value	PGA370 socket not occupied.

Table 42. Signal Description (Sheet 5 of 8)

Name	Type	Description
FLUSH#	I	When the FLUSH# input signal is asserted, processors write back all data in the Modified state from their internal caches and invalidate all internal cache lines. At the completion of this operation, the processor issues a Flush Acknowledge transaction. The processor does not cache any new data while the FLUSH# signal remains asserted. FLUSH# is an asynchronous signal. However, to ensure recognition of this signal following an I/O write instruction, it must be valid along with the TRDY# assertion of the corresponding I/O Write bus transaction. On the active-to-inactive transition of RESET#, each processor samples FLUSH# to determine its power-on configuration. See the *P6 Family of Processors Hardware Developer's Manual* for details.
HIT# HITM#	I/O I/O	The HIT# (Snoop Hit) and HITM# (Hit Modified) signals convey transaction snoop operation results, and must connect the appropriate pins of all processor system bus agents. Any such agent may assert both HIT# and HITM# together to indicate that it requires a snoop stall, which can be continued by reasserting HIT# and HITM# together.
IERR#	O	The IERR# (Internal Error) signal is asserted by a processor as the result of an internal error. Assertion of IERR# is usually accompanied by a SHUTDOWN transaction on the processor system bus. This transaction may optionally be converted to an external error signal (e.g., NMI) by system core logic. The processor will keep IERR# asserted until the assertion of RESET#, BINIT#, or INIT#.
IGNNE#	I	The IGNNE# (Ignore Numeric Error) signal is asserted to force the processor to ignore a numeric error and continue to execute noncontrol floating-point instructions. If IGNNE# is deasserted, the processor generates an exception on a noncontrol floating-point instruction if a previous floating-point instruction caused an error. IGNNE# has no effect when the NE bit in control register 0 is set. IGNNE# is an asynchronous signal. However, to ensure recognition of this signal following an I/O write instruction, it must be valid along with the TRDY# assertion of the corresponding I/O Write bus transaction.
INIT#	I	The INIT# (Initialization) signal, when asserted, resets integer registers inside all processors without affecting their internal (L1 or L2) caches or floating-point registers. Each processor then begins execution at the power-on Reset vector configured during power-on configuration. The processor continues to handle snoop requests during INIT# assertion. INIT# is an asynchronous signal and must connect the appropriate pins of all processor system bus agents. If INIT# is sampled active on the active to inactive transition of RESET#, then the processor executes its Built-in Self-Test (BIST).
LINT[1:0]	I	The LINT[1:0] (Local APIC Interrupt) signals must connect the appropriate pins of all APIC Bus agents, including all processors and the core logic or I/O APIC component. When the APIC is disabled, the LINT0 signal becomes INTR, a maskable interrupt request signal, and LINT1 becomes NMI, a nonmaskable interrupt. INTR and NMI are backward compatible with the signals of those names on the Pentium processor. Both signals are asynchronous. Both of these signals must be software configured via BIOS programming of the APIC register space to be used either as NMI/INTR or LINT[1:0]. Because the APIC is enabled by default after Reset, operation of these pins as LINT[1:0] is the default configuration.
LOCK#	I/O	The LOCK# signal indicates to the system that a transaction must occur atomically. This signal must connect the appropriate pins of all processor system bus agents. For a locked sequence of transactions, LOCK# is asserted from the beginning of the first transaction end of the last transaction. When the priority agent asserts BPRI# to arbitrate for ownership of the processor system bus, it will wait until it observes LOCK# deasserted. This enables symmetric agents to retain ownership of the processor system bus throughout the bus locked operation and ensure the atomicity of lock.

Table 42. Signal Description (Sheet 6 of 8)

Name	Type	Description
PICCLK	I	The PICCLK (APIC Clock) signal is an input clock to the processor and core logic or I/O APIC which is required for operation of all processors, core logic, and I/O APIC components on the APIC bus.
PICD[1:0]	I/O	The PICD[1:0] (APIC Data) signals are used for bidirectional serial message passing on the APIC bus, and must connect the appropriate pins of all processors and core logic or I/O APIC components on the APIC bus.
PLL1, PLL2	I	All Pentium III processors have an internal analog PLL clock generator that requires a quiet power supply. PLL1 and PLL2 are inputs to this PLL and must be connected to $V_{CC_{CORE}}$ through a low pass filter that minimizes jitter. See the platform design guide for implementation details.
PRDY#	O	The PRDY (Probe Ready) signal is a processor output used by debug tools to determine processor debug readiness.
PREQ#	I	The PREQ# (Probe Request) signal is used by debug tools to request debug operation of the processors.
PWRGOOD	I	The PWRGOOD (Power Good) signal is processor input. The processor requires this signal to be a clean indication that the clocks and power supplies ($V_{CC_{CORE}}$, etc.) are stable and within their specifications. Clean implies that the signal will remain low (capable of sinking leakage current), without glitches, from the time that the power supplies are turned on until they come within specification. The signal must then transition monotonically to a high state. The figure below illustrates the relationship of PWRGOOD to other system signals. PWRGOOD can be driven inactive at any time, but clocks and power must again be stable before a subsequent rising edge of PWRGOOD. It must also meet the minimum pulse width specification in Table 19, and be followed by a 1 ms RESET# pulse. The PWRGOOD signal must be supplied to the processor; it is used to protect internal circuits against voltage sequencing issues. It should be driven high throughout boundary scan operation.
REQ[4:0]#	I/O	The REQ[4:0]# (Request Command) signals must connect the appropriate pins of all processor system bus agents. They are asserted by the current bus owner over two clock cycles to define the currently active transaction type.
RESET#	I	Asserting the RESET# signal resets all processors to known states and invalidates their L1 and L2 caches without writing back any of their contents. For a power-on Reset, RESET# must stay active for at least one millisecond after $V_{CC_{CORE}}$ and CLK have reached their proper specifications. On observing active RESET#, all processor system bus agents will deassert their outputs within two clocks. A number of bus signals are sampled at the active-to-inactive transition of RESET# for power-on configuration. These configuration options are described in the *P6 Family of Processors Hardware Developer's Manual* for details. The processor may have its outputs tristated via power-on configuration. Otherwise, if INIT# is sampled active during the active-to-inactive transition of RESET#, the processor will execute its Built-in Self-Test (BIST). Whether or not BIST is executed, the processor will begin program execution at the power on Reset vector (default 0_FFFF_FFF0h). RESET# must connect the appropriate pins of all processor system bus agents.
RESET2#	I	The RESET2# pin is provided for compatibility with other Intel Architecture processors. The Pentium III processor does not use the RESET2# pin. Refer to the platform design guide for the proper connections of this signal.
RP#	I/O	The RP# (Request Parity) signal is driven by the request initiator, and provides parity protection on ADS# and REQ[4:0]#. It must connect the appropriate pins of all processor system bus agents. A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. This definition allows parity to be high when all covered signals are high.
RS[2:0]#	I	The RS[2:0]# (Response Status) signals are driven by the response agent (the agent responsible for completion of the current transaction), and must connect the appropriate pins of all processor system bus agents.

Table 42. Signal Description (Sheet 7 of 8)

Name	Type	Description
RSP#	I	The RSP# (Response Parity) signal is driven by the response agent (the agent responsible for completion of the current transaction) during assertion of RS[2:0]#, the signals for which RSP# provides parity protection. It must connect the appropriate pins of all processor system bus agents. A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. While RS[2:0]# = 000, RSP# is also high, since this indicates it is not being driven by any agent guaranteeing correct parity.
RTTCTRL	I	The RTTCTRL input signal provides AGTL+ termination control. The Pentium III processor samples this input to sense the presence of motherboard AGTL+ termination. See the platform design guide for implementation details.
SLEWCTRL	I	The SLEWCTRL input signal provides AGTL+ slew rate control. The Pentium III processor samples this input to determine the slew rate for AGTL+ signals when it is the driving agent. See the platform design guide for implementation details.
SLP#	I	The SLP# (Sleep) signal, when asserted in Stop-Grant state, causes processors to enter the Sleep state. During Sleep state, the processor stops providing internal clock signals to all units, leaving only the Phase-Locked Loop (PLL) still operating. Processors in this state will not recognize snoops or interrupts. The processor will recognize only assertions of the SLP#, STPCLK#, and RESET# signals while in Sleep state. If SLP# is deasserted, the processor exits Sleep state and returns to Stop-Grant state, restarting its internal clock signals to the bus and APIC processor core units.
SMI#	I	The SMI# (System Management Interrupt) signal is asserted asynchronously by system logic. On accepting a System Management Interrupt, processors save the current state and enter System Management Mode (SMM). An SMI Acknowledge transaction is issued, and the processor begins program execution from the SMM handler.
STPCLK#	I	The STPCLK# (Stop Clock) signal, when asserted, causes processors to enter a low power Stop-Grant state. The processor issues a Stop-Grant Acknowledge transaction, and stops providing internal clock signals to all processor core units except the bus and APIC units. The processor continues to snoop bus transactions and latch interrupts while in Stop-Grant state. When STPCLK# is deasserted, the processor restarts its internal clock to all units, services pending interrupts while in the Stop-Grant state, and resumes execution. The assertion of STPCLK# has no effect on the bus clock; STPCLK# is an asynchronous input.
THERMDN	O	Thermal Diode Cathode. Used to calculate core (junction) temperature. See Section 4.3.
THERMDP	I	Thermal Diode Anode. Used to calculate core (junction) temperature. See Section 4.3.
THERMTRIP#	O	The processor protects itself from catastrophic overheating by use of an internal thermal sensor. This sensor is set well above the normal operating temperature to ensure that there are no false trips. The processor will stop all execution when the junction temperature exceeds approximately 135 °C. This is signaled to the system by the THERMTRIP# (Thermal Trip) pin. Once activated, the signal remains latched, and the processor stopped, until RESET# goes active. There is no hysteresis built into the thermal sensor itself; as long as the die temperature drops below the trip level, a RESET# pulse will reset the processor and execution will continue. If the temperature has not dropped below the trip level, the processor will continue to drive THERMTRIP# and remain stopped. The system designer should not act upon THERMTRIP# until after RESET# input is de-asserted since, until this time, the THERMTRIP# output is indeterminate.
TRDY#	I	The TRDY# (Target Ready) signal is asserted by the target to indicate that it is ready to receive a write or implicit writeback data transfer. TRDY# must connect the appropriate pins of all processor system bus agents.

Table 42. Signal Description (Sheet 8 of 8)

Name	Type	Description
VID[3:0]	O	The VID[3:0] (Voltage ID) pins can be used to support automatic selection of power supply voltages. These pins are not signals, but are either an open circuit or a short circuit to V_{SS} on the processor. The combination of opens and shorts defines the voltage required by the processor. The VID pins are needed to cleanly support voltage specification variations on processors. See Table 2 for definitions of these pins. The power supply must supply the voltage that is requested by these pins, or disable itself.
$VCORE_{DET}$	O	The $VCORE_{DET}$ pin indicate the type of processor core present. This pin will float for 2.0 V VCC_{CORE} based processor and will be shorted to V_{SS} for the Pentium III processor.
$VCC_{1.5}$	I	The $VCC_{1.5}$ V input pin provides the termination voltage for CMOS signals interfacing to the processor. The Pentium III processor reroutes the 1.5 V input to the VCC_{CMOS} output via the package. The supply for $VCC_{1.5}$ V must be the same one used to supply V_{TT}.
$VCC_{2.5}$	I	The $VCC_{2.5}$ V input pin provides the termination voltage for CMOS signals interfacing to processors which require 2.5 V termination on the CMOS signals. This signal is not used by the Pentium III processor.
VCC_{CMOS}	O	The VccCMOS pin provides the CMOS voltage for use by the platform and is used for terminating CMOS signals that interface to the processor.
V_{REF}	I	The V_{REF} input pins supply the AGTL+ reference voltage, which is typically 2/3 of V_{TT}. V_{REF} is used by the AGTL+ receivers to determine if a signal is a logical 0 or a logical 1.

7.2   Signal Summaries

Table 43 through Table 46 list attributes of the processor output, input, and I/O signals.

Table 43. Output Signals

Name	Active Level	Clock	Signal Group
CPUPRES#	Low	Asynch	Power/Other
EDGCTRL	N/A	Asynch	Power/Other
FERR#	Low	Asynch	CMOS Output
IERR#	Low	Asynch	CMOS Output
PRDY#	Low	BCLK	AGTL+ Output
THERMTRIP#	Low	Asynch	CMOS Output
$VCORE_{DET}$	N/A	Asynch	Power/Other
VID[3:0]	N/A	Asynch	Power/Other

Table 44. Input Signals (Sheet 1 of 2)

Name	Active Level	Clock	Signal Group	Qualified
A20M#	Low	Asynch	CMOS Input	Always[1]
BCLK	High	—	System Bus Clock	Always
BPRI#	Low	BCLK	AGTL+ Input	Always
BR1#	Low	BCLK	AGTL+ Input	Always

Table 44. Input Signals (Sheet 2 of 2)

Name	Active Level	Clock	Signal Group	Qualified
DEFER#	Low	BCLK	AGTL+ Input	Always
FLUSH#	Low	Asynch	CMOS Input	Always[1]
IGNNE#	Low	Asynch	CMOS Input	Always[1]
INIT#	Low	Asynch	CMOS Input	Always[1]
INTR	High	Asynch	CMOS Input	APIC disabled mode
LINT[1:0]	High	Asynch	CMOS Input	APIC enabled mode
NMI	High	Asynch	CMOS Input	APIC disabled mode
PICCLK	High	—	APIC Clock	Always
PREQ#	Low	Asynch	CMOS Input	Always
PWRGOOD	High	Asynch	CMOS Input	Always
RESET#	Low	BCLK	AGTL+ Input	Always
RS[2:0]#	Low	BCLK	AGTL+ Input	Always
RSP#	Low	BCLK	AGTL+ Input	Always
RTTCTRL	N/A	Asynch	Power/Other	
SLEWCTRL	N/A	Asynch	Power/Other	
SLP#	Low	Asynch	CMOS Input	During Stop-Grant state
SMI#	Low	Asynch	CMOS Input	
STPCLK#	Low	Asynch	CMOS Input	
TRDY#	Low	BCLK	AGTL+ Input	

NOTE:
1. Synchronous assertion with active TDRY# ensures synchronization.

DEP[7:0]#	Low	BCLK	AGTL+ I/O	DRDY#
DRDY#	Low	BCLK	AGTL+ I/O	Always
LOCK#	Low	BCLK	AGTL+ I/O	Always
REQ[4:0]#	Low	BCLK	AGTL+ I/O	ADS#, ADS#+1
RP#	Low	BCLK	AGTL+ I/O	ADS#, ADS#+1

Table 46. Input/Output Signals (Multiple Driver)

Name	Active Level	Clock	Signal Group	Qualified
AERR#	Low	BCLK	AGTL+ I/O	ADS#+3
BERR#	Low	BCLK	AGTL+ I/O	Always
BINIT#	Low	BCLK	AGTL+ I/O	Always
BNR#	Low	BCLK	AGTL+ I/O	Always
HIT#	Low	BCLK	AGTL+ I/O	Always
HITM#	Low	BCLK	AGTL+ I/O	Always
PICD[1:0]	High	PICCLK	APIC I/O	Always
