ABSOLUTE MAXIMUM RATINGS

Voltage Range on VCC Pin Relative to Grou	
Operating Temperature Range	
Commercial (noncondensing)	0°C to +70°C
Operating Temperature Range	
Industrial (noncondensing)	40°C to +85°C
Storage Temperature Range	
EDIP	40°C to +85°C
PDIP SO PLCC TOFP	-55°C to +125°C

Lead Temperature (soldering, 10s)	+260°C
(Note: EDIP is hand or wave-soldered only.)	
Soldering Temperature (reflow)	
PDIP, SO, PLCC	+260°C
TQFP	+245°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Input and Output Timing Measurement Reference Levels	Input/Output: VIL maximum and VIH minimum
Input-Pulse Rise and Fall Times	5ns

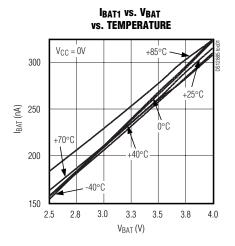

WARNING: Negative undershoots below -0.3V while the part is in battery-backed mode may cause loss of data.

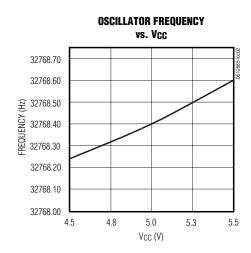

- **Note 1:** RTC modules can be successfully processed through conventional wave-soldering techniques as long as temperature exposure to the lithium energy source contained within does not exceed +85°C. However, post-solder cleaning with waterwashing techniques is acceptable, provided that ultrasonic vibrations are not used to prevent crystal damage.
- **Note 2:** Limits at -40°C are guaranteed by design and not production tested.
- Note 3: All voltages are referenced to ground.
- Note 4: All outputs are open.
- Note 5: Specified with $\overline{CS} = DS = R\overline{W} = \overline{RESET} = V_{CC}$; MOT, AS, AD0-AD7 = 0; V_{BACKUP} open.
- **Note 6:** Applies to the AD0 to AD7 pins, the \overline{IRQ} pin, and the SQW pin when each is in a high-impedance state.
- **Note 7:** The MOT pin has an internal $20k\Omega$ pulldown.
- Note 8: Measured with a 32.768kHz crystal attached to X1 and X2.
- **Note 9:** Guaranteed by design. Not production tested.
- Note 10: Measured with a 50pF capacitance load.

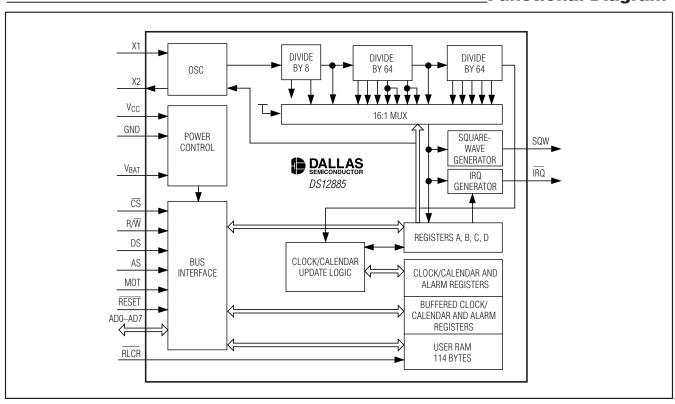

Typical Operating Characteristics

 $(V_{CC} = +5.0V, T_A = +25^{\circ}C, unless otherwise noted.)$

Functional Diagram

Pin Description

	PIN				
SO, PDIP	EDIP	PLCC	TQFP	NAME	FUNCTION
1	1	2	29	MOT	Motorola or Intel Bus Timing Selector. This pin selects one of two bus types. When connected to V _{CC} , Motorola bus timing is selected. When connected to GND or left disconnected, Intel bus timing is selected. The pin has an internal pulldown resistor.
2	_	3	30	X1	Connections for Standard 32.768kHz Quartz Crystal. The internal oscillator circuitry is designed for operation with a crystal having a 6pF specified load
3	_	4	31	X2	capacitance (C _L). Pin X1 is the input to the oscillator and can optionally be connected to an external 32.768kHz oscillator. The output of the internal oscillator, pin X2, is left unconnected if an external oscillator is connected to pin X1.
4–11	4–11	5–10, 12, 14	1, 2, 3, 5, 7, 8, 9, 11	AD0- AD7	Multiplexed, Bidirectional Address/Data Bus. The addresses are presented during the first portion of the bus cycle and latched into the device by the falling edge of AS. Write data is latched by the falling edge of DS (Motorola timing) or the rising edge of R/W (Intel timing). In a read cycle, the device outputs data during the latter portion of DS (DS and R/W high for Motorola timing, DS low and R/W high for Intel timing). The read cycle is terminated and the bus returns to a high-impedance state as DS transitions low in the case of Motorola timing or as DS transitions high in the case of Intel timing.
12, 16	12	15, 20	12, 17	GND	Ground
13	13	16	13	CS	Active-Low Chip-Select Input. The chip-select signal must be asserted low for a bus cycle in the device to be accessed. \overline{CS} must be kept in the active state during DS and AS for Motorola timing and during DS and R/ \overline{W} for Intel timing. Bus cycles that take place without asserting \overline{CS} will latch addresses, but no access occurs. When V_{CC} is below V_{PF} volts, the device inhibits access by internally disabling the \overline{CS} input. This action protects the RTC data and the RAM data during power outages.
14	14	17	14	AS	Address Strobe Input. A positive-going address-strobe pulse serves to demultiplex the bus. The falling edge of AS causes the address to be latched within the device. The next rising edge that occurs on the AS bus clears the address regardless of whether $\overline{\text{CS}}$ is asserted. An address strobe must immediately precede each write or read access. If a write or read is performed with $\overline{\text{CS}}$ deasserted, another address strobe must be performed prior to a read or write access with $\overline{\text{CS}}$ asserted.
15	15	19	16	R/W	Read/Write Input. The R/W pin has two modes of operation. When the MOT pin is connected to V_{CC} for Motorola timing, R/W is at a level that indicates whether the current cycle is a read or write. A read cycle is indicated with a high level on R/W while DS is high. A write cycle is indicated when R/W is low during DS. When the MOT pin is connected to GND for Intel timing, the R/W signal is an active-low signal. In this mode, the R/W pin operates in a similar fashion as the write-enable signal (WE) on generic RAMs. Data are latched on the rising edge of the signal.

Pin Description (continued)

	P	'IN			
SO, PDIP	EDIP	PLCC	TQFP	NAME	FUNCTION
22	2, 3, 16, 20, 21, 22	1, 11, 13, 18, 26	4, 6, 10, 15, 20, 23, 25, 27, 32	N.C.	No Connection. This pin should remain unconnected. Pin 21 is RCLR for the DS12887A/DS12C887A. On the EDIP, these pins are missing by design.
17	17	21	18	DS	Data Strobe or Read Input. The DS pin has two modes of operation depending on the level of the MOT pin. When the MOT pin is connected to V_{CC} , Motorola bus timing is selected. In this mode, DS is a positive pulse during the latter portion of the bus cycle and is called data strobe. During read cycles, DS signifies the time that the device is to drive the bidirectional bus. In write cycles, the trailing edge of DS causes the device to latch the written data. When the MOT pin is connected to GND, Intel bus timing is selected. DS identifies the time period when the device drives the bus with read data. In this mode, the DS pin operates in a similar fashion as the outputenable (\overline{OE}) signal on a generic RAM.
18	18	22	19	RESET	Active-Low Reset Input. The RESET pin has no effect on the clock, calendar, or RAM. On power-up, the RESET pin can be held low for a time to allow the power supply to stabilize. The amount of time that RESET is held low is dependent on the application. However, if RESET is used on power-up, the time RESET is low should exceed 200ms to ensure that the internal timer that controls the device on power-up has timed out. When RESET is low and VCC is above VPF, the following occurs: A. Periodic interrupt-enable (PIE) bit is cleared to 0. B. Alarm interrupt-enable (AIE) bit is cleared to 0. C. Update-ended interrupt-enable (UIE) bit is cleared to 0. D. Periodic-interrupt flag (PF) bit is cleared to 0. E. Alarm-interrupt flag (AF) bit is cleared to 0. G. Interrupt-request status flag (IRQF) bit is cleared to 0. H. IRQ pin is in the high-impedance state. I. The device is not accessible until RESET is returned high. J. Square-wave output-enable (SQWE) bit is cleared to 0. In a typical application, RESET can be connected to VCC. This connection allows the device to go in and out of power fail without affecting any of the control registers.

Pin Description (continued)

	PIN				
SO, PDIP	EDIP	PLCC	TQFP	NAME	FUNCTION
19	19	23	21	ĪRQ	Active-Low Interrupt Request Output. The \overline{IRQ} pin is an active-low output of the device that can be used as an interrupt input to a processor. The \overline{IRQ} output remains low as long as the status bit causing the interrupt is present and the corresponding interrupt-enable bit is set. The processor program normally reads the C register to clear the \overline{IRQ} pin. The \overline{RESET} pin also clears pending interrupts. When no interrupt conditions are present, the \overline{IRQ} level is in the high-impedance state. Multiple interrupting devices can be connected to an \overline{IRQ} bus, provided that they are all open drain. The \overline{IRQ} pin is an open-drain output and requires an external pullup resistor to VCC.
20	_	24	22	V _{BAT}	Connection for a Primary Battery. (DS12885 Only.) Battery voltage must be held between the minimum and maximum limits for proper operation. If a backup supply is not supplied, V _{BAT} must be grounded. Connect the battery directly to the V _{BAT} pin. Diodes in series between the V _{BAT} pin and the battery may prevent proper operation. UL recognized to ensure against reverse charging when used with a lithium battery.
21	21 (DS12887A/ DS12C887A)	25	24	RCLR	Active-Low RAM Clear. The RCLR pin is used to clear (set to logic 1) all the general-purpose RAM, but does not affect the RAM associated with the RTC. To clear the RAM, RCLR must be forced to an input logic 0 during battery-backup mode when VCC is not applied. The RCLR function is designed to be used through a human interface (shorting to ground manually or by a switch) and not to be driven with external buffers. This pin is internally pulled up. Do not use an external pullup resistor on this pin.
23	23	27	26	SQW	Square-Wave Output. The SQW pin can output a signal from one of 13 taps provided by the 15 internal divider stages of the RTC. The frequency of the SQW pin can be changed by programming Register A, as shown in Table 1. The SQW signal can be turned on and off using the SQWE bit in Register B. The SQW signal is not available when VCC is less than VPF.
24	24	28	28	Vcc	DC Power Pin for Primary Power Supply. When V _{CC} is applied within normal limits, the device is fully accessible and data can be written and read. When V _{CC} is below V _{PF} reads and writes are inhibited.

Detailed Description

The DS12885 family of RTCs provide 14 bytes of real-time clock/calendar, alarm, and control/status registers and 114 bytes (113 bytes for DS12C887 and DS12C887A) of nonvolatile, battery-backed static RAM. A time-of-day alarm, three maskable interrupts with a common interrupt output, and a programmable square-wave output are available. The devices also operate in either 24-hour or 12-hour format with an AM/PM indicator. A precision temperature-compensated circuit monitors the status of VCC. If a primary power-supply failure is detected, the devices automatically switch to a back-up supply. The backup supply input supports a primary battery, such as lithium coin cell. The devices are accessed through a multiplexed address/data bus that supports Intel and Motorola modes.

Oscillator Circuit

The DS12885 uses an external 32.768kHz crystal. The oscillator circuit does not require any external resistors or capacitors to operate. Table 1 specifies several crystal parameters for the external crystal. Figure 1 shows a functional schematic of the oscillator circuit. An enable bit in the control register controls the oscillator. Oscillator startup times are highly dependent upon crystal characteristics, PC board leakage, and layout. High ESR and excessive capacitive loads are the major contributors to long startup times. A circuit using a crystal with the recommended characteristics and proper layout usually starts within one second.

An external 32.768kHz oscillator can also drive the DS12885. In this configuration, the X1 pin is connected to the external oscillator signal and the X2 pin is left unconnected.

Table 1. Crystal Specifications*

PARAMETER	SYMBOL	MIN	TYP	MAX	UNITS
Nominal Frequency	fo		32.768		kHz
Series Resistance	ESR			50	kΩ
Load Capacitance	CL		6		рF

^{*}The crystal, traces, and crystal input pins should be isolated from RF generating signals. Refer to Application Note 58: Crystal Considerations for Dallas Real-Time Clocks for additional specifications.

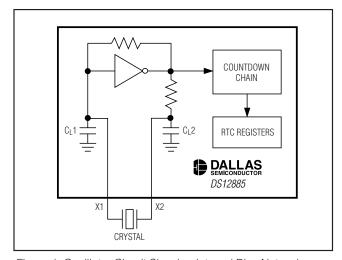

Figure 1. Oscillator Circuit Showing Internal Bias Network

Clock Accuracy

The accuracy of the clock is dependent upon the accuracy of the crystal and the accuracy of the match between the capacitive load of the oscillator circuit and the capacitive load for which the crystal was trimmed. Additional error is added by crystal frequency drift caused by temperature shifts. External circuit noise coupled into the oscillator circuit can result in the clock running fast. Figure 2 shows a typical PC board layout for isolation of the crystal and oscillator from noise. Refer to Application Note 58: Crystal Considerations with Dallas Real-Time Clocks for more detailed information.

Clock Accuracy for DS12887, DS12887A, DS12C887, DS12C887A Only

The encapsulated DIP modules are trimmed at the factory to an accuracy of ± 1 minute per month at $+25^{\circ}$ C.

Power-Down/Power-Up Considerations

The real-time clock continues to operate, and the RAM, time, calendar, and alarm memory locations remain nonvolatile regardless of the V_{CC} input level. V_{BAT} must remain within the minimum and maximum limits when V_{CC} is not applied. When V_{CC} is applied and exceeds V_{PF} (power-fail trip point), the device becomes accessible after t_{REC}—if the oscillator is running and the oscillator countdown chain is not in reset (Register A). This time allows the system to stablize after power is applied. If the oscillator is not enabled, the oscillatorenable bit is enabled on power-up, and the device becomes immediately accessible.

Time, Calendar, and Alarm Locations

The time and calendar information is obtained by reading the appropriate register bytes. The time, calendar, and alarm are set or initialized by writing the appropriate register bytes. Invalid time or date entries result in undefined operation. The contents of the 10 time, calendar, and alarm bytes can be either binary or binary-coded decimal (BCD) format.

The day-of-week register increments at midnight, incrementing from 1 through 7. The day-of-week register is used by the daylight saving function, so the value 1 is defined as Sunday. The date at the end of the month is

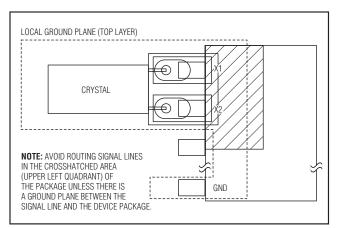

Figure 2. Layout Example

automatically adjusted for months with fewer than 31 days, including correction for leap years.

Before writing the internal time, calendar, and alarm registers, the SET bit in Register B should be written to logic 1 to prevent updates from occurring while access is being attempted. In addition to writing the 10 time, calendar, and alarm registers in a selected format (binary or BCD), the data mode bit (DM) of Register B must be set to the appropriate logic level. All 10 time, calendar, and alarm bytes must use the same data mode. The SET bit in Register B should be cleared after the data mode bit has been written to allow the RTC to update the time and calendar bytes. Once initialized, the RTC makes all updates in the selected mode. The data mode cannot be changed without reinitializing the 10 data bytes. Tables 2A and 2B show the BCD and binary formats of the time, calendar, and alarm locations.

The 24-12 bit cannot be changed without reinitializing the hour locations. When the 12-hour format is selected, the higher-order bit of the hours byte represents PM when it is logic 1. The time, calendar, and alarm bytes are always accessible because they are double-buffered. Once per second the seven bytes are advanced by one second and checked for an alarm condition.

If a read of the time and calendar data occurs during an update, a problem exists where seconds, minutes, hours, etc., may not correlate. The probability of reading incorrect time and calendar data is low. Several methods of avoiding any possible incorrect time and calendar reads are covered later in this text.

The three alarm bytes can be used in two ways. First, when the alarm time is written in the appropriate hours, minutes, and seconds alarm locations, the alarm interrupt is initiated at the specified time each day, if the alarm-enable bit is high. In this mode, the "0" bits in the alarm registers and the corresponding time registers must always be written to 0 (Table 2A and 2B). Writing the 0 bits in the alarm and/or time registers to 1 can result in undefined operation.

The second use condition is to insert a "don't care" state in one or more of the three alarm bytes. The don't-care code is any hexadecimal value from C0 to FF. The two most significant bits of each byte set the don't-care

condition when at logic 1. An alarm is generated each hour when the don't-care bits are set in the hours byte. Similarly, an alarm is generated every minute with don't-care codes in the hours and minute alarm bytes. The don't-care codes in all three alarm bytes create an interrupt every second.

All 128 bytes can be directly written or read, except for the following:

- 1) Registers C and D are read-only.
- 2) Bit 7 of register A is read-only.
- 3) The MSB of the seconds byte is read-only.

Table 2A. Time, Calendar, and Alarm Data Modes—BCD Mode (DM = 0)

ADDRESS	BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0	FUNCTION	RANGE

X = Read/Write Bit.

Note: Unless otherwise specified, the state of the registers is not defined when power is first applied. Except for the seconds register, 0 bits in the time and date registers can be written to 1, but may be modified when the clock updates. 0 bits should always be written to 0 except for alarm mask bits.

^{*}DS12C887, DS12C887A only. General-purpose RAM on DS12885, DS12887, and DS12887A.

_Control Registers

The real-time clocks have four control registers that are accessible at all times, even during the update cycle.

Control Register A

MSB LSB

BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
UIP	DV2	DV1	DV0	RS3	RS2	RS1	RS0

Bit 7: Update-In-Progress (UIP). This bit is a status flag that can be monitored. When the UIP bit is a 1, the update transfer occurs soon. When UIP is a 0, the update transfer does not occur for at least 244µs. The time, calendar, and alarm information in RAM is fully available for access when the UIP bit is 0. The UIP bit is read-only and is not affected by RESET. Writing the SET bit in Register B to a 1 inhibits any update transfer and clears the UIP status bit.

Bits 6, 5, and 4: DV2, DV1, DV0. These three bits are used to turn the oscillator on or off and to reset the countdown chain. A pattern of 010 is the only combination of bits that turn the oscillator on and allow the RTC to keep time. A pattern of 11x enables the oscillator but holds the countdown chain in reset. The next update occurs at 500ms after a pattern of 010 is written to DV0, DV1, and DV2.

Bits 3 to 0: Rate Selector (RS3, RS2, RS1, RS0). These four rate-selection bits select one of the 13 taps on the 15-stage divider or disable the divider output. The tap selected can be used to generate an output square wave (SQW pin) and/or a periodic interrupt. The user can do one of the following:

- 1) Enable the interrupt with the PIE bit;
- 2) Enable the SQW output pin with the SQWE bit;
- Enable both at the same time and the same rate;
 or
- 4) Enable neither.

Table 3 lists the periodic interrupt rates and the square-wave frequencies that can be chosen with the RS bits. These four read/write bits are not affected by RESET.

Control Register B

MSB LSB

BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
SET	PIE	AIE	UIE	SQWE	DM	24/12	DSE

Bit 7: SET. When the SET bit is 0, the update transfer functions normally by advancing the counts once per second. When the SET bit is written to 1, any update transfer is inhibited, and the program can initialize the time and calendar bytes without an update occurring in the midst of initializing. Read cycles can be executed in a similar manner. SET is a read/write bit and is not affected by RESET or internal functions of the device.

Bit 6: Periodic Interrupt Enable (PIE). The PIE bit is a read/write bit that allows the periodic interrupt flag (PF) bit in Register C to drive the IRQ pin low. When the PIE bit is set to 1, periodic interrupts are generated by driving the IRQ pin low at a rate specified by the RS3–RS0 bits of Register A. A 0 in the PIE bit blocks the IRQ output from being driven by a periodic interrupt, but the PF bit is still set at the periodic rate. PIE is not modified by any internal device functions, but is cleared to 0 on RESET.

Bit 5: Alarm Interrupt Enable (AIE). This bit is a read/write bit that, when set to 1, permits the alarm flag (AF) bit in Register C to assert IRQ. An alarm interrupt occurs for each second that the three time bytes equal the three alarm bytes, including a don't-care alarm code of binary 11XXXXXX. The AF bit does not initiate the IRQ signal when the AIE bit is set to 0. The internal functions of the device do not affect the AIE bit, but is cleared to 0 on RESET.

Bit 4: Update-Ended Interrupt Enable (UIE). This bit is a read/write bit that enables the update-end flag (UF) bit in Register C to assert IRQ. The RESET pin going low or the SET bit going high clears the UIE bit.

The internal functions of the <u>device</u> do not affect the UIE bit, but is cleared to 0 on RESET.

Bit 3: Square-Wave Enable (SQWE). When this bit is set to 1, a square-wave signal at the frequency set by the rate-selection bits RS3–RS0 is driven out on the SQW pin. When the SQWE bit is set to 0, the SQW pin is held low. SQWE is a read/write bit and is cleared by RESET. SQWE is low if disabled, and is high impedance when VCC is below VPF. SQWE is cleared to 0 on RESET.

Bit 2: Data Mode (DM). This bit indicates whether time and calendar information is in binary or BCD format. The DM bit is set by the program to the appropriate format and can be read as required. This bit is not modified by internal functions or RESET. A 1 in DM signifies binary data, while a 0 in DM specifies BCD data.

Bit 1: 24/12. The 24/12 control bit establishes the format of the hours byte. A 1 indicates the 24-hour mode and a 0 indicates the 12-hour mode. This bit is read/write and is not affected by internal functions or RESET.

Bit 0: Daylight Saving Enable (DSE). This bit is a read/write bit that enables two daylight saving adjustments when DSE is set to 1. On the first Sunday in April, the time increments from 1:59:59 AM to 3:00:00 AM. On the last Sunday in October when the time first reaches 1:59:59 AM, it changes to 1:00:00 AM. When DSE is enabled, the internal logic test for the first/last Sunday condition at midnight. If the DSE bit is not set when the test occurs, the daylight saving function does not operate correctly. These adjustments do not occur when the DSE bit is 0. This bit is not affected by internal functions or RESET.

Control Register C

MSB LSB

BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
IRQF	PF	AF	UF	0	0	0	0

Bit 7: Interrupt Request Flag (IRQF). This bit is set to 1 when any of the following are true:

PF = PIE = 1

AF = AIE = 1

UF = UIE = 1

Any time the IRQF bit is 1, the $\overline{\text{IRQ}}$ pin is driven low. This bit can be cleared by reading Register C or with a $\overline{\text{RESET}}$.

Bit 6: Periodic Interrupt Flag (PF). This bit is readonly and is set to 1 when an edge is detected on the selected tap of the divider chain. The RS3 through RS0 bits establish the periodic rate. PF is set to 1 independent of the state of the PIE bit. When both PF and PIE are 1s, the \overline{IRQ} signal is active and sets the IRQF bit. This bit can be cleared by reading Register C or with a \overline{RESET} .

Bit 5: Alarm Interrupt Flag (AF). A 1 in the AF bit indicates that the current time has matched the alarm time. If the AIE bit is also 1, the IRQ pin goes low and a 1 appears in the IRQF bit. This bit can be cleared by reading Register C or with a RESET.

Bit 5: Update-Ended Interrupt Flag (UF). This bit is set after each update cycle. When the UIE bit is set to 1, the 1 in <u>UF</u> causes the IRQF bit to be a 1, which asserts the <u>IRQ</u> pin. <u>This bit</u> can be cleared by reading Register C or with a <u>RESET</u>.

Bits 3 to 0: Unused. These bits are unused in Register C. These bits always read 0 and cannot be written.

Control Register D

MSB LSB

BIT 7	BIT 6	BIT 5	BIT 4	BIT 3	BIT 2	BIT 1	BIT 0
VRT	0	0	0	0	0	0	0

Bit 7: Valid RAM and Time (VRT). This bit indicates the condition of the battery connected to the V_{BAT} pin. This bit is not writeable and should always be 1 when read. If a 0 is ever present, an exhausted internal lithium energy source is indicated and both the contents of

the RTC data and \overline{RAM} data are questionable. This bit is unaffected by \overline{RESET} .

Bits 6 to 0: Unused. The remaining bits of Register D are not usable. They cannot be written and they always read 0.

Century Register (DS12C887/DS12C887A Only)

The century register at location 32h is a BCD register designed to automatically load the BCD value 20 as the year register changes from 99 to 00. The MSB of this register is not affected when the load of 20 occurs, and remains at the value written by the user.

Nonvolatile RAM (NV RAM)

The general-purpose NV RAM bytes are not dedicated to any special function within the device. They can be used by the processor program as battery-backed memory and are fully available during the update cycle.

Interrupts

The RTC family includes three separate, fully automatic sources of interrupt for a processor. The alarm interrupt can be programmed to occur at rates from once per second to once per day. The periodic interrupt can be selected for rates from 500ms to 122µs. The update-ended interrupt can be used to indicate to the program that an update cycle is complete. Each of these independent interrupt conditions is described in greater detail in other sections of this text.

The processor program can select which interrupts, if any, are to be used. Three bits in Register B enable the interrupts. Writing a logic 1 to an interrupt-enable bit permits that interrupt to be initiated when the event occurs. A 0 in an interrupt-enable bit prohibits the $\overline{\mbox{IRQ}}$ pin from being asserted from that interrupt condition. If an interrupt flag is already set when an interrupt is enabled, $\overline{\mbox{IRQ}}$ is immediately set at an active level, although the interrupt initiating the event may have occurred earlier. As a result, there are cases where the program should clear such earlier initiated interrupts before first enabling new interrupts.

When an interrupt event occurs, the relating flag bit is set to logic 1 in Register C. These flag bits are set independent of the state of the corresponding enable bit in Register B. The flag bit can be used in a polling mode without enabling the corresponding enable bits. The interrupt flag bit is a status bit that software can interrogate as necessary. When a flag is set, an indication is given to software that an interrupt event has occurred since the flag bit was last read; however, care should be taken when using the flag bits as they are cleared each time Register C is read. Double latching is included with Register C so that bits that are set remain stable throughout the read cycle. All bits that are set (high) are cleared when read, and new interrupts that are pending during the read cycle are held until after the cycle is completed. One, two, or three bits can be set when reading Register C. Each used flag bit should be examined when Register C is read to ensure that no interrupts are lost.

The second flag bit method is used with fully enabled interrupts. When an interrupt flag bit is set and the corresponding interrupt-enable bit is also set, the \overline{IRQ} pin is asserted low. \overline{IRQ} is asserted as long as at least one of the three interrupt sources has its flag and enable bits set. The IRQF bit in Register C is a 1 whenever the \overline{IRQ} pin is driven low. Determination that the RTC initiated an interrupt is accomplished by reading Register C. A logic 1 in bit 7 (IRQF bit) indicates that one or more interrupts have been initiated by the device. The act of reading Register C clears all active flag bits and the IRQF bit.

Oscillator Control Bits

When the DS12887, DS12887A, DS12C887, and DS12C887A are shipped from the factory, the internal oscillator is turned off. This prevents the lithium energy cell from being used until the device is installed in a system.

A pattern of 010 in bits 4 to 6 of Register A turns the oscillator on and enables the countdown chain. A pattern of 11x (DV2 = 1, DV1 = 1, DV0 = X) turns the oscillator on, but holds the countdown chain of the oscillator in reset. All other combinations of bits 4 to 6 keep the oscillator off.

Square-Wave Output Selection

Thirteen of the 15 divider taps are made available to a 1-of-16 multiplexer, as shown in the functional diagram. The square-wave and periodic-interrupt generators share the output of the multiplexer. The RS0–RS3 bits in Register A establish the output frequency of the multiplexer (see Table 1). Once the frequency is selected, the output of the SQW pin can be turned on and off under program control with the square-wave enable bit, SQWE.

Periodic Interrupt Selection

The periodic interrupt causes the $\overline{\text{IRQ}}$ pin to go to an active state from once every 500ms to once every 122µs. This function is separate from the alarm interrupt, which can be output from once per second to once per day. The periodic interrupt rate is selected using the same Register A bits that select the square-wave frequency (Table 1). Changing the Register A bits affects the square-wave frequency and the periodic-interrupt output. However, each function has a separate enable bit in Register B. The SQWE bit controls the square-wave output. Similarly, the PIE bit in Register B enables the periodic interrupt. The periodic interrupt can be used with software counters to measure inputs, create output intervals, or await the next needed software function.

Table 3. Periodic Interrupt Rate and Square-Wave Output Frequency

:	SELEC REGIS	T BITS TER A		t _{PI} PERIODIC INTERRUPT	SQW OUTPUT FREQUENCY
RS3	RS2	RS1	RS0	RATE	THEGOLINGT
0	0	0	0	None	None
0	0	0	1	3.90625ms	256Hz
0	0	1	0	7.8125ms	128Hz
0	0	1	1	122.070µs	8.192kHz
0	1	0	0	244.141µs	4.096kHz
0	1	0	1	488.281µs	2.048kHz
0	1	1	0	976.5625µs	1.024kHz
0	1	1	1	1.953125ms	512Hz
1	0	0	0	3.90625ms	256Hz
1	0	0	1	7.8125ms	128Hz
1	0	1	0	15.625ms	64Hz
1	0	1	1	31.25ms	32Hz
1	1	0	0	62.5ms	16Hz
1	1	0	1	125ms	8Hz
1	1	1	0	250ms	4Hz
1	1	1	1	500ms	2Hz

Update Cycle

The device executes an update cycle once per second regardless of the SET bit in Register B. When the SET bit in Register B is set to 1, the user copy of the double-buffered time, calendar, and alarm bytes is frozen and does not update as the time increments. However, the time countdown chain continues to update the internal copy of the buffer. This feature allows time to maintain accuracy independent of reading or writing the time, calendar, and alarm buffers, and also guarantees that time and calendar information is consistent. The update cycle also compares each alarm byte with the corre-

sponding time byte and issues an alarm if a match or if a don't-care code is present in all three positions.

There are three methods that can handle RTC access that avoid any possibility of accessing inconsistent time and calendar data. The first method uses the update-ended interrupt. If enabled, an interrupt occurs after every update cycle that indicates over 999ms is available to read valid time and date information. If this interrupt is used, the IRQF bit in Register C should be cleared before leaving the interrupt routine.

A second method uses the update-in-progress bit (UIP) in Register A to determine if the update cycle is in progress. The UIP bit pulses once per second. After the UIP bit goes high, the update transfer occurs 244µs later. If a low is read on the UIP bit, the user has at least 244µs before the time/calendar data is changed. Therefore, the user should avoid interrupt service routines that would cause the time needed to read valid time/calendar data to exceed 244µs.

The third method uses a periodic interrupt to determine if an update cycle is in progress. The UIP bit in Register A is set high between the setting of the PF bit in Register C (Figure 3). Periodic interrupts that occur at a rate greater than tBUC allow valid time and date information to be reached at each occurrence of the periodic interrupt. The reads should be complete within one (tPI/2 + tBUC) to ensure that data is not read during the update cycle.

Handling, PC Board Layout, ____and Assembly

The EDIP module can be successfully processed through conventional wave-soldering techniques so long as temperature exposure to the lithium energy source does not exceed +85°C. Post-solder cleaning with waterwashing techniques is acceptable, provided that ultrasonic vibration is not used. Such cleaning can damage the crystal.

Revision History

REVISION NUMBER	REVISION DATE	DESCRIPTION	PAGES CHANGED
0	6/05	Initial release of combined data sheet	_
1	4/06	Corrected the Intel Bus Write Timing, Intel Bus Read Timing, IRQ Release Delay Timing, Power-Up/Down Timing, and Functional Diagram diagrams; added the Handling, PC Board Layout, and Assembly section.	4, 5, 7, 20
2	5/06	Corrected the <i>Intel Bus Write Timing</i> diagram; added PLCC pin description information; changed pin 16 from N.C. to GND for the SO and PDIP packages.	4, 8, 9, 10, 20
3	2/07	Corrected the Intel Bus Write Timing diagram; updated the Ordering Information; added the Package Information table; removed the package drawings.	4, 20, 22–27
4	4/10	Updated the storage temperature ranges, added the lead temperature, and updated the soldering temperature for all packages in the <i>Absolute Maximum Ratings</i> ; removed leaded parts from the <i>Ordering Information</i> table.	2, 21
