

ABSOLUTE MAXIMUM RATINGS (Beyond which damage may occur)¹ 25°C

Supply Voltages (Measured to GND)

Positive Supply Voltage (AV_{CC})	-0.5 to +11.0 V
Negative Supply Voltage (AV_{EE})	-11.0 to +0.5 V
Negative Supply Voltage (DV_{EE})	-6.0 to +0.5 V

Input Voltages

Input Common Mode Voltage	$DV_{EE}-1$ to $+AV_{CC}+1$
Differential Input Voltage	-12.0 to +12.0 V
Input Voltage, Latch Controls	DV_{EE} to 0.5 V
V_{IN} to AV_{CC} Differential Voltage	-16 to +1.0 V
V_{IN} to AV_{EE} Differential Voltage	+4 to +21.0 V

Output

Output Current	30 mA
----------------	-------

Temperature

Operating Temperature, ambient	0 to +70 °C
junction	+150 °C
Lead Temperature, (soldering 60 seconds)	+300 °C
Storage Temperature	-65 to +150 °C

Note: 1. Operation at any Absolute Maximum Rating is not implied. See Electrical Specifications for proper nominal applied conditions in typical applications. Application of multiple maximum rating conditions at the same time may damage the device.

ELECTRICAL SPECIFICATIONS

$T_A = +25\text{ °C}$, $AV_{CC} = +10\text{ V}$, $AV_{EE} = -10.0\text{ V}$, $DV_{EE} = -5.2\text{ V}$, $R_L = 50\text{ Ohm}$ to -2V , unless otherwise specified.

Fall Time	20% to 80%	V		0.4		ns
Slew Rate		V		3		V/ns

NOTES:

¹ Valid for both high-to-low and low-to-high transitions.

² Dispersion is the change in propagation delay due to changes in slew rate, overdrive, and common mode level.

TEST LEVEL CODES

All electrical characteristics are subject to the following conditions:

All parameters having min/max specifications are guaranteed. The Test Level column indicates the specific device testing actually performed during production and Quality Assurance inspection. Any blank section in the data column indicates that the specification is not tested at the specified condition.

TEST LEVEL

TEST PROCEDURE

I	100% production tested at the specified temperature.
II	100% production tested at $T_A = 25\text{ }^\circ\text{C}$, and sample tested at the specified temperatures.
III	QA sample tested only at the specified temperatures.
IV	Parameter is guaranteed (but not tested) by design and characterization data.
V	Parameter is a typical value for information purposes only.
VI	100% production tested at $T_A = 25\text{ }^\circ\text{C}$. Parameter is guaranteed over specified temperature range.

TIMING INFORMATION

The timing diagram for the comparator is shown in figure 1. If LE is high and \overline{LE} low in the SPT9691, the comparator tracks the input difference voltage. When LE is driven low and \overline{LE} high, the comparator outputs are latched into their existing logic states.

The leading edge of the input signal (which consists of a 150 mV overdrive voltage) changes the comparator output after a time of t_{pdL} or t_{pdH} (Q or \overline{Q}). The input signal must be maintained for a time t_s (set-up time) before the LE falling edge and \overline{LE} rising edge and held for time t_H after the falling edge for the comparator to accept data. After t_H , the output ignores the input status until the latch is strobed again. A minimum latch pulse width of t_{pL} is needed for strobe operation, and the output transitions occur after a time of t_{pLOH} or t_{pLOL} .

Figure 1 - Timing Diagram

The set-up and hold times are a measure of the time required for an input signal to propagate through the first stage of the comparator to reach the latching circuitry. Input signals occurring before t_s will be detected and held; those occurring after t_H will not be detected. Changes between t_s and t_H may not be detected.

SWITCHING TERMS (Refer to figure 1)

t_{pdH} INPUT TO OUTPUT HIGH DELAY - The propagation delay measured from the time the input signal crosses the reference voltage (\pm the input offset voltage) to the 50% point of an output LOW to HIGH transition.

t_{pdL} INPUT TO OUTPUT LOW DELAY - The propagation delay measured from the time the input signal crosses the reference voltage (\pm the input offset voltage) to the 50% point of an output HIGH to LOW transition.

t_{pLOH} LATCH ENABLE TO OUTPUT HIGH DELAY - The propagation delay measured from the 50% point of the Latch Enable signal LOW to HIGH transition to 50% point of an output LOW to HIGH transition.

t_{pLOL} LATCH ENABLE TO OUTPUT LOW DELAY - The propagation delay measured from the 50% point of the Latch Enable signal LOW to HIGH transition to the 50% point of an output HIGH to LOW transition.

t_H MINIMUM HOLD TIME - The minimum time after the negative transition of the Latch Enable signal that the input signal must remain unchanged in order to be acquired and held at the outputs.

t_{pL} MINIMUM LATCH ENABLE PULSE WIDTH - The minimum time that the Latch Enable signal must be HIGH in order to acquire an input signal change.

t_s MINIMUM SET-UP TIME - The minimum time before the negative transition of the Latch Enable signal that an input signal change must be present in order to be acquired and held at the outputs.

V_{OD} VOLTAGE OVERDRIVE - The difference between the differential input and reference input voltages.

TYPICAL PERFORMANCE CURVES

HYSTERESIS VS ΔLATCH

GENERAL INFORMATION

The SPT9691 is an ultrahigh-speed dual voltage comparator. It offers tight absolute characteristics. The device has differential analog inputs and complementary logic outputs compatible with ECL systems. The output stage is adequate for driving terminated 50 ohm transmission lines.

The SPT9691 has a complementary latch enable control for each comparator. Both should be driven by standard ECL logic levels.

A common mode voltage range of -4 V to +8 V is achieved by a proprietary JFET input design which requires a separate negative power supply (AV_{EE}).

The dual comparators have separate AV_{CC} , AV_{EE} , DV_{EE} , and grounds for each comparator to achieve high crosstalk rejection. Single channel operation can be accomplished by floating all pins (including the ground and supply pins) of the unused comparator. Power dissipation during single channel operation is 50% of the dissipation during dual channel operation.

Figure 2 - Internal Function Diagram

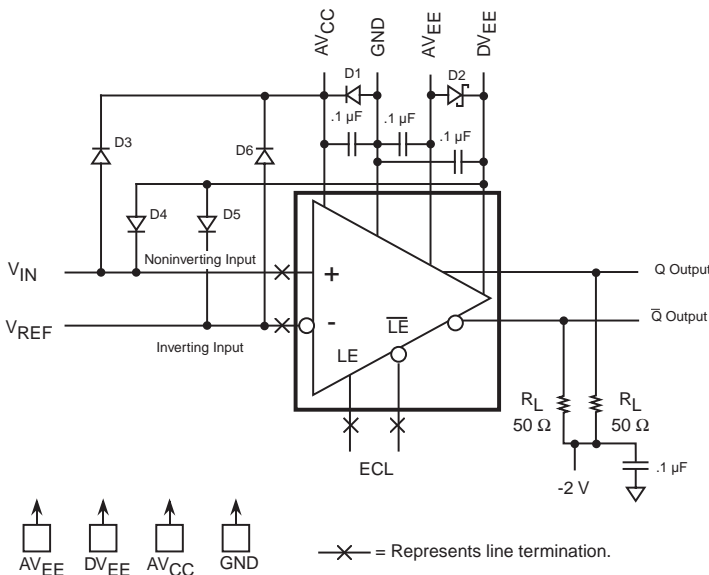

TYPICAL INTERFACE CIRCUIT

The typical interface circuit using the comparator is shown in figure 3. Although it needs few external components and is easy to apply, there are several conditions that should be noted to achieve optimal performance. The very high operating speeds of the comparator require careful layout, decoupling of supplies, and proper design of transmission lines.

Since the SPT9691 comparator is a very high frequency and high gain device, certain layout rules must be followed to avoid oscillations. The comparator should be soldered to the board with component lead lengths kept as short as possible. A ground plane should be used, while the input impedance to the part is kept as low as possible, to decrease parasitic feedback. If the output board traces are longer than approximately half an inch, microstripline techniques must be employed to prevent ringing on the output waveform. Also, the microstriplines must be terminated at the far end with the characteristic impedance of the line to prevent reflections. All supply voltage pins should be decoupled with high frequency capacitors as close to the device as possible. All ground pins should be connected to the same ground plane to further improve noise immunity and shielding. If using the SPT9691 as a single comparator, the outputs of the inactive comparator can be grounded, left open or terminated with 50 Ohms to

Figure 3 - SPT9691 Typical Interface Circuit

-2 V. All outputs on the active comparator, whether used or unused, should have identical terminations to minimize ground current switching transients.

Diode D1 connected between AV_{CC} and GND is recommended to prevent possible damage to the device in case the AV_{CC} supply is disconnected. The diode should be a 1N914 or equivalent. If AV_{CC} is disconnected with this diode in place, there will be approximately a 6 mA current draw from both AV_{EE} and DV_{EE} . Diode D2 connected between AV_{EE} and DV_{EE} is necessary to avoid power supply sequence latch-up. This diode keeps AV_{EE} (also the substrate) less than a silicon diode drop away from the most negative circuit potential if DV_{EE} is powered up first. This diode should be a 1N5817 (Schottky) or equivalent.

Note: At no time should both inputs be allowed to float with power applied to the device. At least one of the inputs should be tied to a voltage within the common mode range (-4.0 to +8.0 V) to prevent possible damage to the device. To prevent possible latch-up during initial power up, the input voltages should not exceed ± 1 V. Additional protection diodes D3-D6 should be used on the inputs if there is the possibility of exceeding the absolute maximum ratings of the inputs with respect to AV_{CC} and DV_{EE} (1N914 or equivalent). NOTE: For ease of implementation, all diodes (D1 - D6) can be 1N5817 (Schottky) or equivalent.
