5.1 Application circuit

5.2 Mode selection

The three operating modes of the TDA7498 are set by the two inputs, STBY (pin 20) and MUTE (pin 21).

- Standby mode: all circuits are turned off, very low current consumption.
- Mute mode: inputs are connected to ground and the positive and negative PWM outputs are at 50% duty cycle.
- Play mode: the amplifiers are active.

The protection functions of the TDA7498 are enabled by pulling down the voltages of the STBY and MUTE inputs shown in Figure 20. Standby and mute circuits. The input current of the corresponding pins must be limited to 200 µA.

Table 6. Mode settings

Mode	STBY	MUTE
Standby	L (1)	X (don't care)
Mute	H (1)	L
Play	H	H

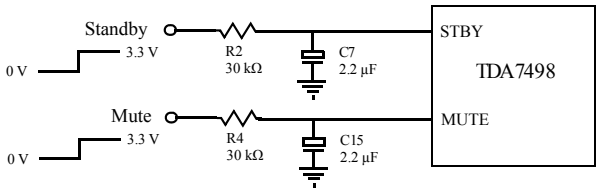

Figure 21. **Turn on/off sequence for minimizing speaker "pop"**

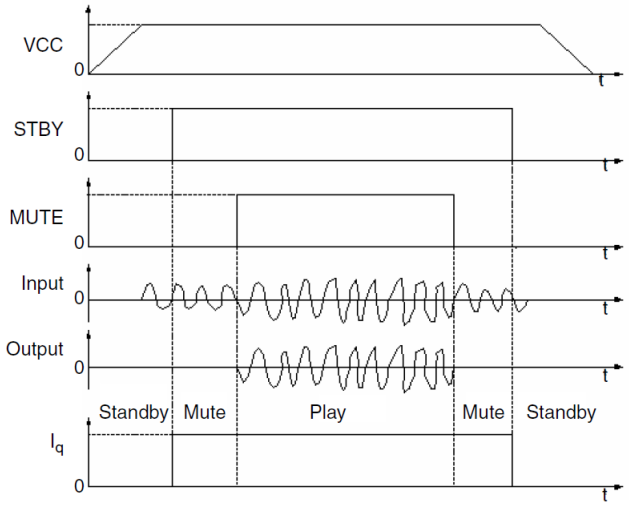


5.3 Gain setting

The gain of the TDA7498 is set by the two inputs, GAIN0 (pin 30) and GAIN1 (pin31). Internally, the gain is set by changing the feedback resistors of the amplifier.

Table 7. **Gain settings**

GAIN0	GAIN1	Nominal gain, G_V (dB)
L	L	25.6
L	H	31.6
H	L	35.6
H	H	37.6

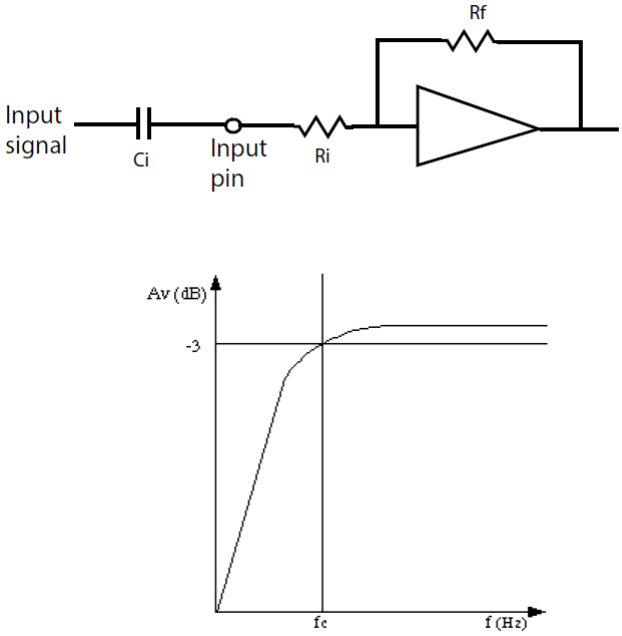
5.4 Input resistance and capacitance

The input impedance is set by an internal resistor Ri = 60 kΩ (typical). An input capacitor (Ci) is required to couple the AC input signal.

The equivalent circuit and frequency response of the input components are shown in Figure 22. Input circuit and frequency response. For Ci = 470 nF the high-pass filter cutoff frequency is below 20 Hz:

$f_C = 1 / (2 * \pi * Ri * Ci)$

Figure 22. **Input circuit and frequency response**



5.5 Internal and external clocks

The clock of the class-D amplifier can be generated internally or can be driven by an external source.

If two or more class-D amplifiers are used in the same system, it is recommended that all devices operate at the same clock frequency. This can be implemented by using one TDA7498 as master clock, while the other devices are in slave mode, that is, externally clocked. The clock interconnect is via pin SYNCLK of each device. As explained below, SYNCLK is an output in master mode and an input in slave mode.

5.5.1 Master mode (internal clock)

Using the internal oscillator, the output switching frequency, f_{SW}, is controlled by the resistor, R_{OSC}, connected to pin ROSC:

$f_{SW} = 10^6 / [(R_{OSC} * 16 + 182) * 4]$ kHz

where R_{OSC} is in kΩ.

In master mode, pin SYNCLK is used as a clock output pin whose frequency is:

$f_{SYNCLK} = 2 * f_{SW}$

For master mode to operate correctly then resistor R_{OSC} must be less than 60 kΩ as given below in Table 8. How to set up SYNCLK.

5.5.2 Slave mode (external clock)

In order to accept an external clock input the pin ROSC must be left open, that is, floating. This forces pin SYNCLK to be internally configured as an input as given in Table 8. How to set up SYNCLK.

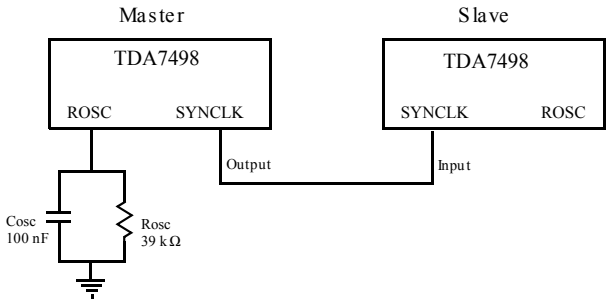
The output switching frequency of the slave devices is:

$f_{SW} = f_{SYNCLK} / 2$

Table 8. **How to set up SYNCLK**

Mode	ROSC	SYNCLK
Master	R_{OSC} < 60 kΩ	Output
Slave	Floating (not connected)	Input

Figure 23. **Master and slave connection**



5.6 Output low-pass filter

To avoid EMI problems, it may be necessary to use a low-pass filter before the speaker. The cutoff frequency should be larger than 22 kHz and much lower than the output switching frequency. It is necessary to choose the L and C component values depending on the loudspeaker impedance. Some typical values, which give a cutoff frequency of 27 kHz, are shown in Figure 24. Typical LC filter for an 8 Ω speaker and Figure 25. Typical LC filter for a 6 Ω speaker below.

Figure 24. **Typical LC filter for an 8 Ω speaker**

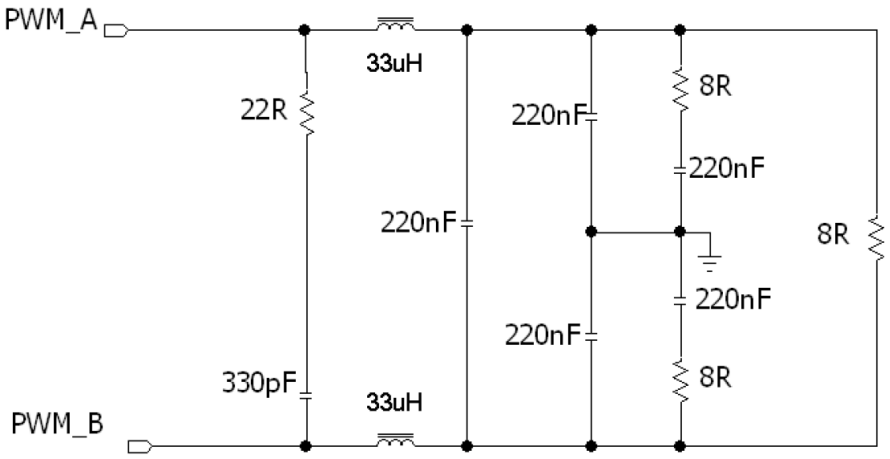


Figure 25. **Typical LC filter for a 6 Ω speaker**

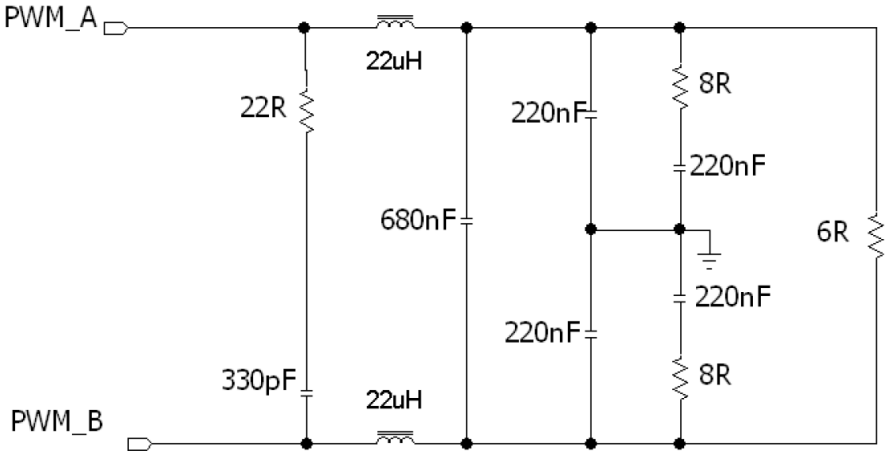

5.7 Protection functions

The TDA7498 is fully protected against overvoltages, undervoltages, overcurrents and thermal overloads as explained here.

Overvoltage protection (OVP)

If the supply voltage exceeds the value for V_{OVP} given in Table 5. Electrical specifications , the overvoltage protection is activated which forces the outputs to the high-impedance state. When the supply voltage falls back to within the operating range, the device restarts.

Undervoltage protection (UVP)

If the supply voltage drops below the value for V_{UVP} given in Table 5. Electrical specifications , the undervoltage protection is activated which forces the outputs to the high-impedance state. When the supply voltage falls back to within the operating range, the device restarts.

Overcurrent protection (OCP)

If the output current exceeds the value for I_{OCP} given in Table 5. Electrical specifications , the overcurrent protection is activated which forces the outputs to the high-impedance state. Periodically, the device attempts to restart. If the overcurrent condition is still present, then the OCP remains active. The restart time, T_{OC}, is determined by the RC components connected to pin STBY.

Thermal protection (OTP)

If the junction temperature, T_j, reaches 145 °C (nominally), the device goes to mute mode and the positive and negative PWM outputs are forced to 50% duty cycle. If the junction temperature reaches the value for T_j given in Table 5. Electrical specifications , the device shuts down and the output is forced to the high-impedance state. When the device cools sufficiently the device restarts.

5.8 Diagnostic output

The output pin DIAG is an open-drain transistor. When any protection is activated, it switches to the high-impedance state. The pin can be connected to a power supply (< 39 V) by a pull-up resistor whose value is limited by the maximum sinking current (200 µA) of the pin.
