28V Internal Switch LCD Bias Supply with True Shutdown

ABSOLUTE MAXIMUM RATINGS

V_{CC}, FB, BATT, SW to GND ....-0.3V to +6V
BATT to SW ....-0.3V to +6V
$\overline{SHDN}$, LIM to GND....................................-0.3 to (V_{CC} + 0.3V)
LX to GND ....-0.3V to +30V
Current into LX or BATT...600mA$_{RMS}$
Current out of SW ....600mA$_{RMS}$
Output Short-Circuit Duration ....Indefinite

Continuous Power Dissipation (T_A = +70°C)
    8-Pin μMAX (derate 4.1mW/°C above +70°C).............330mW
Operating Temperature Range ....-40°C to +85°C
Junction Temperature...+150°C
Storage Temperature Range ....-65°C to +150°C
Lead Temperature (soldering, 10s) ....+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(V_{CC} = 3.3V, V_{CC} = BATT = $\overline{SHDN}$, **T_A = 0°C to +85°C**, unless otherwise noted. Typical values are at T_A = +25°C.)

Pin Description

| PIN	NAME	FUNCTION
1	BATT	Inductor Supply Voltage, 0.8V to 5.5V. Internally connected to the source of a P-channel MOSFET used to isolate the output from the input during shutdown. Bypass with a 10µF or greater capacitor.
2	FB	Feedback Input. Connect to a resistive divider network between the output and GND to set the output voltage between V_{BATT} and 28V. The feedback threshold is 1.25V.
3	V_{CC}	IC Supply Voltage, 2.4V to 5.5V. Bypass V_{CC} to GND with a 1µF or greater capacitor.
4	GND	Ground
5	LX	Inductor Switching Connection. Internally connected to the drain of a 28V N-channel MOSFET. LX is high impedance in shutdown.
6	LIM	Inductor Current-Limit Selection. Connect LIM to V_{CC} for 500mA, leave LIM floating for 250mA, or connect LIM to GND for 125mA.
7	$\overline{SHDN}$	Active-Low Shutdown Input. A logic low shuts down the device and reduces the supply current to 0.1µA. When shutdown, the MAX1606 isolates the output from the input by turning off the P-channel MOSFET between BATT and SW. Connect $\overline{SHDN}$ to V_{CC} for normal operation.
8	SW	Isolation Switch Output, Inductor Connection. Internally connected to the drain of a P-channel MOSFET used to isolate the output from the input during shutdown.

MAX1606

Figure 1. Functional Diagram

Figure 2. Setting the Peak Inductor Current Limit

Detailed Description

The MAX1606 step-up DC-DC converter operates from a 2.4V to 5.5V supply and converts voltages as low as 0.8V up to 28V. The device includes an internal switching MOSFET with a 0.8Ω on-resistance and selectable current limit (Figure 1) and consumes 160µA of supply current. During startup, the MAX1606 extends the minimum off-time, limiting initial battery surge current. The MAX1606 uses a P-channel MOSFET to isolate the output from the input during true shutdown mode. This isolation switch also includes short-circuit current limiting, which protects the inductor and diode during a short-circuit fault.

Control Scheme

The MAX1606 features a minimum off-time, current-limited control scheme. The duty cycle is governed by a pair of one-shots that set a minimum off-time and a maximum on-time. The switching frequency can be up to 500kHz and depends upon the load and input voltage. The peak current limit of the internal N-channel MOSFET is pin selectable and may be set at 125mA, 250mA, or 500mA (Figure 2).
Figure 3. Typical Application Circuit

Setting the Output Voltage (FB)

Adjust the output voltage by connecting a voltage-divider from the output (V_{OUT}) to FB (Figure 3). Select R2 between 10kΩ and 200kΩ. Calculate R1 with the following equation:

$$R1 = R2 [(V_{OUT} / V_{FB}) - 1]$$

where V_{FB} = 1.25V and V_{OUT} may range from V_{BATT} to 28V. The input bias current of FB has a maximum value of 100nA, which allows large-value resistors to be used. For less than 1% error, the current through R2 should be greater than 100 times the feedback input bias current (I_{FB}).

Current-Limit Select Pin (LIM)

The MAX1606 allows a selectable inductor current limit of 125mA, 250mA, or 500mA (Figure 2). This allows flexibility in designing for higher current applications or for smaller, compact designs. The lower current limit allows the use of a physically smaller inductor in space-sensitive, low-power applications. Connect LIM to V_{CC} for 500mA, leave floating for 250mA, or connect to GND for 125mA.

Shutdown (SHDN̄)

Pull SHDN̄ low to enter shutdown. During shutdown the supply current drops to 0.1µA, the output is disconnected from the input, and LX enters a high-impedance state. The capacitance and load at the output determine the rate at which V_{OUT} decays. SHDN̄ can be pulled as high as 6V, regardless of the input and output voltages.

With the typical step-up converter circuit, the output remains connected to the input through the inductor and

output rectifier, holding the output voltage to one diode drop below V_{IN} when the converter is shutdown and allowing the output to draw power from the input. The MAX1606 features true shutdown, which uses an internal P-channel MOSFET to disconnect the output from the input when the MAX1606 is shutdown. This eliminates power drawn from the input during shutdown.

Separate/Same Power for V_{BATT} and V_{CC}

Separate voltage sources can supply the inductor (V_{BATT}) and the IC (V_{CC}). Since the chip bias is provided by a logic supply (2.4V to 5.5V), this allows the output power to be sourced directly from low-voltage batteries (0.8V to 5.5V). Conversely, V_{BATT} and V_{CC} can also be supplied from one supply if it remains within V_{CC}'s operating limits (2.4V to 5.5V).

Design Procedure

Inductor Selection

Smaller inductance values typically offer smaller physical size for a given series resistance or saturation current. Circuits using larger inductance values may start up at lower input voltages and exhibit less ripple, but also provide reduced output power. This occurs when the inductance is sufficiently large to prevent the maximum current limit from being reached before the maximum on-time expires. The inductor's saturation current rating should be greater than the peak switching current. However, it is generally acceptable to bias the inductor into saturation by as much as 20%, although this will slightly reduce efficiency.

Picking the Current Limit

The peak LX current limit ($I_{LX(MAX)}$) required for the application may be calculated from the following equation:

$$I_{LX(MAX)} \geq \frac{V_{OUT} \times I_{OUT(MAX)}}{V_{BATT(MIN)}} + \frac{\left(V_{OUT} - V_{BATT(MIN)}\right) \times t_{OFF(MIN)}}{2 \times L}$$

where $t_{OFF(MIN)}$ = 0.8µs, and $V_{BATT(MIN)}$ is the minimum voltage used to supply the inductor. The set current limit must be greater than this calculated value. Select the appropriate current limit by connecting LIM to V_{CC}, GND, or leaving it unconnected (see *Current-Limit Select Pin* and Figure 2).

Diode Selection

The high switching frequency of 500kHz requires a high-speed rectifier. Schottky diodes, such as the Motorola MBRS0530 or the Nihon EP05Q03L, are recommended. To maintain high efficiency, the average current rating of the Schottky diode should be greater than the peak
Figure 4. Negative Voltage for LCD Bias

switching current. Choose a reverse breakdown voltage greater than the output voltage.

Capacitors

For most applications, use a small 1µF ceramic surface-mount output capacitor. For small ceramic capacitors, the output ripple voltage is dominated by the capacitance value. If tantalum or electrolytic capacitors are used, the higher ESR increases the output ripple voltage. Decreasing the ESR reduces the output ripple voltage and the peak-to-peak transient voltage. Surface-mount capacitors are generally preferred because they lack the inductance and resistance of their through-hole equivalents.

Two inputs, V_{CC} and V_{BATT}, require bypass capacitors. Bypass V_{CC} with a 1µF ceramic capacitor as close to the IC as possible. The BATT input supplies high currents to the inductor and requires local bulk bypassing close to the inductor. A 10µF low-ESR surface-mount capacitor is sufficient for most applications.

A feed-forward capacitor connected from the output to FB improves stability over a wide range of battery voltages. A 10pF capacitor is sufficient for most applications. Larger values (up to 47pF) may be needed with lower current-limit settings (LIM = GND or open) and low input voltages, or with nonoptimum PC board layouts. Note that increasing C_{FF} may slightly affect load regulation.

PC Board Layout and Grounding

Careful printed circuit layout is important for minimizing ground bounce and noise. Keep the MAX1606's ground pin and the ground leads of the input and output capacitors less than 0.2in (5mm) apart. In addition, keep all connections to FB and LX as short as possible.

In particular, external feedback resistors should be as close to FB as possible. To minimize output voltage ripple, and to maximize output power and efficiency, use a ground plane and solder GND directly to the ground plane. Refer to the MAX1606EVKIT evaluation kit for a layout example.

Applications Information

Negative Voltage for LCD Bias

The MAX1606 can also generate a negative output by adding a diode-capacitor charge-pump circuit (D1, D2, and C3) to the LX pin as shown in Figure 4. Feedback is still connected to the positive output, which is not loaded, allowing a very small capacitor value at C4. For best stability and lowest ripple, the time constant of the R1-R2 series combination and C4 should be near or less than that of C2 and the effective load resistance. Output load regulation of the negative output is somewhat looser than with the standard positive output circuit, and may rise at very light loads due to coupling through the capacitance of D2. If this is objectionable, reduce the resistance of R1 and R2, while maintaining their ratio, to effectively preload the output with a few hundred microamps. This is why the R1-R2 values shown in Figure 4 are about four-times lower than typical values used for a positive-output design. When loaded, the negative output voltage will be slightly lower (closer to ground by approximately a diode forward voltage) than the inverse of the voltage on C4.
