

Absolute Maximum Ratings

Terminal Voltage (with respect to GND),
All Pins Except SHUNT -0.3V to (V_{SHUNT} + 0.3V)
Input Current (I_{SHUNT}) 60mA
Output Current (RESET/RESET) 20mA
Short-Circuit Duration Continuous

Continuous Power Dissipation
SOT23-3 (derate 4mW/°C above +70°C) 320mW
Operating Temperature Range -40°C to +85°C
Storage Temperature Range -65°C to +160°C
Lead Temperature (soldering, 10sec) +300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Electrical Characteristics

(I_{SHUNT} = 1mA, C_L = 0.1µF, T_A = -40°C to +85°C, unless otherwise noted. Typical values are at T_A = +25°C.)

PARAMETER	SYMBOL	CONDITIONS		MIN	TYP	MAX	UNITS

Electrical Characteristics (continued)

(I_{SHUNT} = 1mA, C_L = 0.1µF, T_A = -40°C to +85°C, unless otherwise noted. Typical values are at T_A = +25°C.)

RESET/ $\overline{\text{RESET}}$ Output Voltage Low (Note 4)	VOL	I _{SINK} = 3.2mA	MAX6330L, V _{TH(min)}	0.4	V
			MAX6331L, V _{TH(max)}		
		I _{SINK} = 1.2mA	MAX6330T/S, V _{TH(min)}	0.3	
			MAX6331T/S, V _{TH(max)}		
		MAX6330, V _{SHUNT} = 1V, I _{SINK} = 50µA, T _A = 0°C to +70°C			
MAX6330, V _{SHUNT} = 1.2V, I _{SINK} = 50µA, T _A = -40°C to +85°C			0.3		
RESET/ $\overline{\text{RESET}}$ Output Voltage High (Note 4)	VOH	I _{SOURCE} = 800µA	MAX6331L, V _{TH(min)}	0.8 x V _{SHUNT}	V
			MAX6330L, V _{TH(max)}		
		I _{SOURCE} = 500µA	MAX6331T/S, V _{TH(min)}	0.8 x V _{SHUNT}	
			MAX6330T/S, V _{TH(max)}		
		MAX6331, 1.8V < V _{SHUNT} < V _{TH(min)} , I _{SOURCE} = 150µA			

Note 1: It is recommended that the regulation voltage be measured using a 4-wire force-sense technique when operating at high shunt currents. For operating at elevated temperatures, the device must be derated based on a +150°C maximum allowed junction temperature and a maximum thermal resistance of 0.25°C/mW junction to ambient when soldered on a printed circuit board. The T_A = +25°C specification over load is measured using a pulse test at 50mA with less than 5ms on time.

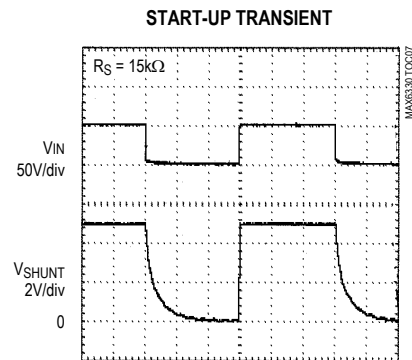

Note 2: Minimum shunt current required for regulated V_{SHUNT}.

Note 3: Maximum shunt current required for regulated V_{SHUNT}.

Note 4: In a typical application where SHUNT serves as the system voltage regulator, note that both I_{SOURCE} for V_{OH} and I_{SINK} for V_{OL} come from V_{SHUNT} (see the *Typical Operating Circuit*).

Typical Operating Characteristics

(Typical Operating Circuit, $C_L = 0.1\mu\text{F}$, $I_{\text{LOAD}} = 0\text{mA}$, $T_A = +25^\circ\text{C}$, unless otherwise noted.)

Pin Description

PIN		NAME	FUNCTION
MAX6330	MAX6331		
1	1	GND	Ground
2	—	$\overline{\text{RESET}}$	Inverting Reset Output. $\overline{\text{RESET}}$ remains low while V_{SHUNT} is below the reset threshold and for 140ms after V_{SHUNT} rises above the threshold.
—	2	RESET	Noninverting Reset Output. RESET remains high while V_{SHUNT} is below the reset threshold and for 140ms after V_{SHUNT} rises above the threshold.
3	3	SHUNT	Regulated Shunt Voltage (+5V, +3.3V, or +3.0V)

Detailed Description

Reset Output

A microprocessor's (μP 's) reset input starts the μP in a known state. The MAX6330/MAX6331 μP supervisory circuits assert reset to prevent code-execution errors during power-up, power-down, or brownout conditions.

$\overline{\text{RESET}}$ is guaranteed to be a logic low for $V_{\text{SHUNT}} > 1\text{V}$. Once V_{SHUNT} exceeds the reset threshold, an internal timer keeps $\overline{\text{RESET}}$ low for the reset timeout period; after this interval, $\overline{\text{RESET}}$ goes high.

If a brownout condition occurs (V_{SHUNT} dips below the reset threshold), $\overline{\text{RESET}}$ goes low. When V_{SHUNT} falls below the reset threshold, the internal timer resets to zero and $\overline{\text{RESET}}$ goes low. The internal timer starts after V_{SHUNT} returns above the reset threshold, and $\overline{\text{RESET}}$ then remains low for the reset timeout period.

The MAX6331 has an active-high RESET output that is the inverse of the MAX6330's $\overline{\text{RESET}}$ output.

Shunt Regulator

The shunt regulator consists of a pass device and a controlling circuit, as illustrated in Figure 1. The pass device allows the regulator to sink current while regulating the desired output voltage within a $\pm 1.5\%$ tolerance. The shunt current range (I_{SHUNT}) is $100\mu\text{A}$ to 50mA .

The pass transistor in the MAX6330/MAX6331 maintains a constant output voltage (V_{SHUNT}) by sinking the necessary amount of shunt current. When I_{LOAD} (see *Typical Operating Circuit*) is at a maximum, the shunt current is at a minimum, and vice versa:

$$I_{\text{IN}} = I_{\text{SHUNT}} + I_{\text{LOAD}} = (V_{\text{IN}} - V_{\text{SHUNT}}) / R_{\text{S}}$$

Consider the following information when choosing the external resistor R_{S} :

- 1) The input voltage range, (V_{IN})
- 2) The regulated voltage, (V_{SHUNT})
- 3) The output current range, (I_{LOAD})

Choose R_{S} as follows:

$$(V_{\text{IN}(\text{max})} - V_{\text{SHUNT}(\text{min})}) / (50\text{mA} + I_{\text{LOAD}(\text{min})}) \leq R_{\text{S}} \leq (V_{\text{IN}(\text{min})} - V_{\text{SHUNT}(\text{max})}) / (100\mu\text{A} + I_{\text{LOAD}(\text{max})})$$

Choose the largest nominal resistor value for R_{S} that gives the lowest current consumption. Provide a safety margin to incorporate the worst-case tolerance of the

Figure 1. Functional Diagram

resistor used. Ensure that the resistor’s power rating is adequate, using the following general power equation:

$$P_R = I_{IN}(V_{IN(max)} - V_{SHUNT}) = I_{IN}^2 R_S = (V_{IN(max)} - V_{SHUNT})^2 / R_S$$

Applications Information

Negative-Going VSHUNT Transients

In addition to issuing a reset to the μP during power-up, power-down, and brownout conditions, the MAX6330/MAX6331 are relatively immune to short-duration negative-going VSHUNT transients (glitches). Additional bypass filter capacitance mounted close to the SHUNT pin provides additional transient immunity.

Choosing the Bypass Capacitor, CL

The bypass capacitor (CL) on the SHUNT pin can significantly affect the device’s load-transient response, so choose it carefully. When a load transient occurs, the current for this load is diverted from the shunt regulator.

The maximum load current that can be diverted from the regulator is:

$$I_{LOAD} \text{ (diverted from regulator)} = I_{SHUNT(max)} - I_{SHUNT(min)} = 50\text{mA} - 100\mu\text{A} = 49.9\text{mA}$$

The shunt regulator has a finite response to this transient. The instantaneous requirements of the load change are met by the charge on CL, resulting in overshoot/undershoot on VSHUNT. The magnitude of this overshoot/undershoot increases with ISHUNT and decreases with CL. When VSHUNT undershoots, the shunt current decreases to where it will only draw quiescent current (IQ), and the shunt element turns off. At this point, VSHUNT will slew toward VIN at the following rate:

$$\Delta V_{SHUNT} / \Delta t = (I_{IN} - I_{LOAD} - 60\mu\text{A}) / C_L$$

As VSHUNT rises, it will turn on the shunt regulator when it can sink 100μA of current. A finite response time for the shunt regulator to start up will result in a brief overshoot of VSHUNT before it settles into its regulation voltage. Therefore, ILOAD should always be 100μA or more below IIN, or VSHUNT will not recover to its regulation point. To prevent this condition, be sure to select the correct series-resistor RS value (see the Shunt Regulator section).

Figures 2, 3, and 4 show load-transient responses for different choices of bypass capacitors on VSHUNT. These photos clearly illustrate the benefits and drawbacks of the capacitor options. A smaller bypass

Figure 2. Load-Transient Response with CL = 0.22µF

Figure 3. Load-Transient Response with CL = 0.033µF

Figure 4. Load-Transient Response with CL = 0.0047µF

capacitor allows a sharper drop in V_{SHUNT} when the load transient occurs, and will suffer from a steeper overshoot when the device re-enters regulation. On the other hand, the increased compensation on a larger bypass capacitor will lead to a longer recovery time to regulation. The *Typical Operating Characteristics* graph Overshoot vs. Bypass Capacitance (C_L) illustrates this trade-off.

If the compensation of the bypass capacitor chosen is insufficient, the output (V_{SHUNT}) can oscillate. Before choosing a bypass capacitor for the desired shunt current, observe the stability boundary conditions indicated in the *Typical Operating Characteristics*. The minimum output capacitance is $0.03\mu F$ to ensure stability over the full load-current range.

Adding Hysteresis

In certain circumstances, the MAX6330 can be trapped in a state that forces it to enter into and exit from a reset condition indefinitely. This usually occurs in systems where V_{SHUNT} is just below the device’s trip threshold and the system draws less quiescent current under reset conditions than when operating out of reset. The difference in supply current when the device is in or out of reset can translate to a significant change in the voltage drop across R_S , which the MAX6330’s built-in hysteresis may not overcome. A $100k\Omega$ pull-up resistor will overcome this condition and add hysteresis (Figure 5).

Figure 5. Adding Hysteresis to the MAX6330

Note that adding this pull-up resistor to the MAX6330 will render \overline{RESET} invalid with $V_{SHUNT} < 1V$, since this output loses sinking capability at this point, and the pull-up resistor would invalidate the signal. This does not present a problem in most applications, since most μP s and other circuitry are inoperative when V_{SHUNT} is below $1V$.

Interfacing to μP s with Bidirectional Reset Pins

Microprocessors with bidirectional reset pins (such as the Motorola 68HC11 series) can contend with MAX6330’s reset output. If, for example, the MAX6330’s \overline{RESET} output is asserted high and the μP wants to pull it low, indeterminate logic levels may result. To correct this, connect a $4.7k\Omega$ resistor between the \overline{RESET} output and the μP reset I/O (Figure 6). Buffer the \overline{RESET} output to other system components. Also, R_S must be sized to compensate for additional current drawn by the μP during the fault condition.

Shunt Current Effects on V_{SHUNT} and V_{TH}

When sinking large shunt currents, power dissipation heats the die to temperatures greater than ambient. This may cause the V_{SHUNT} and V_{TH} tolerances to approach $\pm 3\%$ at high ambient temperatures and high shunt currents. Limit the die temperature to less than $+150^\circ C$ using $\Theta_{JA} = 0.25^\circ C/mW$.
