### PIN FUNCTION DESCRIPTION

Pin	Type	Symbol	Description
1	I	IN_R	Negative input of the second amplifier. It receives the audio input signal. Connected to the input capacitor $C_{in}$ (NCP2809A) or the external $R_{in}$ (NCP2809B).
2	I	SHUTDOWN	The device enters in shutdown mode when a low level is applied on this pin.
3	I	BYPASS	Bypass capacitor pin which provides the common mode voltage ( $V_P/2$ ).
4	O	REF_I	Virtual ground amplifier feed back. This pin sets the stereo headset ground. In order to improve crosstalk, this pin must be connected as close as possible to the ground connection of the headset (ideally at the ground pin of the headset connector). When one uses bypassing capacitors, this pin must be left unconnected.
5	I	IN_L	Negative input of the first amplifier. It receives the audio input signal. Connected to the input capacitor $C_{in}$ (NCP2809A) or the external $R_{in}$ (NCP2809B).
6	O	OUT_L	Stereo headset amplifier analog output left. This pin will output the amplified analog signal and, depending on the application, must be coupled with a capacitor or directly connected to the left loudspeaker of the headset. This output is able to drive a 16 $\Omega$ load in a single-ended configuration.
7	I	$V_P$	Positive analog supply of the cell. Range: 2.2 V – 5.5 V
8	O	OUT_I	Virtual ground for stereo Headset common connection. This pin is directly connected to the common connection of the headset when use of bypassing capacitor is not required. When one uses bypassing capacitors, this pin must be left unconnected.
9	I	$V_M$	Analog Ground
10	O	OUT_R	Stereo headset amplifier analog output right. This pin will output the amplified analog signal and, depending on the application, must be coupled with a capacitor or directly connected to the right loudspeaker of the headset. This output is able to drive a 16 $\Omega$ load in a single-ended configuration.

### MAXIMUM RATINGS ( $T_A = +25^\circ\text{C}$ )

Rating	Symbol	Value	Unit	
Supply Voltage	$V_P$	6.0	V	
Operating Supply Voltage	$O_p V_P$	2.2 to 5.5	V	
Input Voltage	$V_{in}$	-0.3 to $V_{CC} + 0.3$	V	
Max Output Current	$I_{out}$	250	mA	
Power Dissipation	$P_d$	Internally Limited	-	
Operating Ambient Temperature	$T_A$	-40 to +85	$^\circ\text{C}$	
Max Junction Temperature	$T_J$	150	$^\circ\text{C}$	
Storage Temperature Range	$T_{stg}$	-65 to +150	$^\circ\text{C}$	
Thermal Resistance, Junction-to-Air	Micro10 UDFN	$R_{\theta JA}$	200 240	$^\circ\text{C}/\text{W}$
ESD Protection	Human Body Model (HBM) (Note 1) Machine Model (MM) (Note 2)	-	8000 200	V
Latch up current at $T_a = 85^\circ\text{C}$ (Note 3)			$\pm 100$	mA

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

- Human Body Model, 100 pF discharged through a 1.5 k $\Omega$  resistor following specification JESD22/A114 8.0 kV can be applied on OUT\_L, OUT\_R, REF\_I and OUT\_I outputs. For other pins, 2.0 kV is the specified voltage.
- Machine Model, 200 pF discharged through all pins following specification JESD22/A115.
- Maximum ratings per JEDEC standard JESD78.

\*This device contains 752 active transistors and 1740 MOS gates.

## NCP2809 Series

**ELECTRICAL CHARACTERISTICS** All the parameters are given in the capless configuration (typical application). The following parameters are given for the NCP2809A and NCP2809B mounted externally with 0 dB gain, unless otherwise noted. (For typical values  $T_A = 25^\circ\text{C}$ , for min and max values  $T_A = -40^\circ\text{C}$  to  $85^\circ\text{C}$ ,  $T_{Jmax} = 125^\circ\text{C}$ , unless otherwise noted.)

Characteristic	Symbol	Conditions	Min (Note 4)	Typ	Max (Note 4)	Unit
Supply Quiescent Current	$I_{DD}$	$V_{in} = 0\text{ V}$ , $R_L = 16\ \Omega$ $V_p = 2.4\text{ V}$ $V_p = 5.0\text{ V}$		1.54 1.84	2.8 3.6	mA
Output Offset Voltage	$V_{off}$	$V_p = 2.4\text{ V}$ $V_p = 5.0\text{ V}$	-25	1.0	+25	mV

APPLICATION INFORMATION

**Detailed Description**

The NCP2809 power audio amplifier can operate from 2.6 V to 5.0 V power supply. It delivers 24 mW<sub>rms</sub> output power to a 16 Ω load (V<sub>P</sub> = 2.4 V) and 131 mW<sub>rms</sub> output power to a 16 Ω load (V<sub>P</sub> = 5.0 V).

The structure of NCP2809 is basically composed of two identical internal power amplifiers; NCP2809A has a fixed internal gain of 0 dB and the gain can be set externally with the NCP2809B.

**Internal Power Amplifier**

The output P<sub>mos</sub> and N<sub>mos</sub> transistors of the amplifier are designed to deliver the specified output power without clipping. The channel resistance (R<sub>on</sub>) of the N<sub>mos</sub> and P<sub>mos</sub> transistors does not exceed 3.0 Ω when driving current.

The structure of the internal power amplifier is composed of three symmetrical gain stages, first and medium gain stages are transconductance gain stages in order to maximize bandwidth and DC gain.

**Turn-On and Turn-Off Transitions**

A Turn-on/off transition is shown in the following plot corresponding to curves in Figures 38 to 41.

In order to eliminate “pop and click” noises during transitions, output power in the load must be slowly established or cut. When logic high is applied to the shutdown pin, the bypass voltage begins to rise exponentially and once the output DC level is around the common mode voltage, the gain is established slowly (50 ms). This way to turn-on the device is optimized in terms of rejection of “pop and click” noises.

A theoretical value of turn-on time at 25°C is given by the following formula.

C<sub>by</sub>: Bypass Capacitor

R: Internal 300 k resistor with a 25% accuracy

$$T_{on} = 0.95 * R * C_{by}$$

When logic is turned low on shutdown pin, the device enters in shutdown mode:

– 50 ms later the audio signal is cut off as the gain is turned to zero internally as shown in Figure 41.

– 385 ms later, the DC signal will reach 0.7 V due to exponential discharge of the bypass voltage. It is then tied to Ground as shown in Figure 40.

A theoretical approach of this time is:

$$T_{off} = R * C_{by} * \ln(V_p/1.4)$$

**Shutdown Function**

The device enters shutdown mode when shutdown signal is low. During the shutdown mode, the DC quiescent current of the circuit does not exceed 600 nA.

**Current Limit Protection Circuitry**

The maximum output power of the circuit (P<sub>O<sub>rms</sub></sub> = 135 mW, V<sub>P</sub> = 5.0 V, R<sub>L</sub> = 16 Ω) requires a peak current in the load of 130 mA.

In order to limit excessive power dissipation in the load when a short-circuit occurs, the current limit in the load is fixed to 250 mA. The current in the output MOS transistors is real-time monitored, and when exceeding 250 mA, the gate voltage of the corresponding MOS transistor is clipped and no more current can be delivered.

**Thermal Overload Protection Circuitry**

Internal amplifiers are switched off when temperature exceeds 160°C, and will be switched back on only when the temperature goes below 140°C.

NCP2809 is a stereo power audio amplifier.

If the application requires a Single Ended topology with output coupling capacitors, then the current provided by the battery for one output is as following:

- V<sub>O</sub>(t) is the AC voltage seen by the load. Here we consider a sine wave signal with a period T and a peak voltage V<sub>O</sub>.
- R<sub>L</sub> is the load.

So, the total power delivered by the battery to the device is:

$$P_{TOT} = V_p \times I_{pavg}$$

$$I_{pavg} = \frac{1}{2\pi} \times \int_0^\pi \frac{V_O}{R_L} \sin(t) dt = \frac{V_O}{\pi \cdot R_L}$$

$$P_{TOT} = \frac{V_p \cdot V_O}{\pi \cdot R_L}$$

The power in the load is P<sub>OUT</sub>.

$$P_{OUT} = \frac{V_O^2}{2R_L}$$

## NCP2809 Series

The dissipated power by the device is

$$P_D = P_{TOT} - P_{OUT}$$

$$P_D = \frac{V_O}{R_L} \times \left[ \frac{V_P}{\pi} - \frac{V_O}{2} \right]$$

At a given power supply voltage, the maximum power dissipated is:

$$P_{Dmax} = \frac{V_P^2}{2\pi^2 \cdot R_L}$$

Of course, if the device is used in a typical stereo application, each load with the same output power will give the same dissipated power. Thus the total lost power for the device is:

$$P_D = \frac{V_O}{R_L} \times \left[ \frac{2V_P}{\pi} - V_O \right]$$

And in this case, the maximum power dissipated will be:

$$P_{Dmax} = \frac{V_P^2}{\pi^2 \cdot R_L}$$

In single ended operation, the efficiency is:

$$\eta = \frac{\pi \cdot V_O}{2V_P}$$

If the application requires a NOCAP scheme without output coupling capacitors, then the current provided by the battery for one output is as following:

- $V_O(t)$  is the AC voltage seen by the load. Here we consider a sine wave signal with a period  $T$  and a peak voltage  $V_O$ .
- $R_L$  is the load.

So, the total power delivered by the battery to the device is:

$$P_{TOT} = V_P \times I_{pavg}$$

$$I_{pavg} = \frac{1}{\pi} \times \int_0^{\pi} \frac{V_O}{R_L} \sin(t) dt = \frac{2V_O}{\pi \cdot R_L}$$

$$P_{TOT} = \frac{2V_P \cdot V_O}{\pi \cdot R_L}$$

The power in the load is  $P_{OUT}$

$$P_{OUT} = \frac{V_O^2}{2R_L}$$

The dissipated power by the device is

$$P_D = P_{TOT} - P_{OUT}$$

$$P_D = \frac{V_O}{R_L} \times \left[ \frac{2V_P}{\pi} - \frac{V_O}{2} \right]$$

At a given power supply voltage, the maximum power dissipated happens when  $V_O = V_P/2$ .

$$P_{Dmax} = \frac{0.19V_P^2}{R_L}$$

Of course, if the device is used in a typical stereo application, each load with the same output power will give the same dissipated power. Thus the total lost power for the device is:

$$P_D = \frac{V_O}{R_L} \times \left[ \frac{4V_P}{\pi} - V_O \right]$$

And in this case, the maximum power dissipated will be:

$$P_{Dmax} = \frac{0.38V_P^2}{R_L}$$

In NOCAP operation, the efficiency is:

$$\eta = \frac{\pi \cdot V_O}{4V_P}$$

### Gain-Setting Selection

With NCP2809 Audio Amplifier family, you can select a closed-loop gain of 0db for the NCP2809A and an external gain setting with the NCP2809B. In order to optimize device and system performance, NCP2809 needs to be used in low gain configurations. It minimizes THD+N values and maximizes the signal-to-noise ratio, and the amplifier can still be used without running into the bandwidth limitations.

NCP2809A can be used when a 0 dB gain is required. Adjustable gain is available on NCP2809B.

### NCP2809 Amplifier External Components

#### Input Capacitor Selection ( $C_{in}$ )

The input coupling capacitor blocks the DC voltage at the amplifier input terminal. This capacitor creates a high-pass filter with the internal (A version with 20 k $\Omega$ ) or external (B version) resistor. Its cut-off frequency is given by:

$$f_c = \frac{1}{2 * \pi * R_{in} * C_{in}} \quad (\text{eq. 1})$$

The size of the capacitor must be large enough to couple in low frequencies without severe attenuation. However a large input coupling capacitor requires more time to reach its quiescent DC voltage ( $V_P/2$ ) and can increase the turn-on pops.

An input capacitor value of 100 nF performs well in many applications (in case of  $R_{in} = 20$  k $\Omega$ ).

### Bypass Capacitor Selection ( $C_{bypass}$ )

The bypass capacitor  $C_{by}$  provides half-supply filtering and determines how fast the NCP2809 turns on.

A proper supply bypassing is critical for low noise performance and high power supply rejection ratio.

Moreover, this capacitor is a critical component to minimize the turn-on pop noise. A 1.0  $\mu$ F bypass capacitor value should produce clickless and popless shutdown transitions. The amplifier is still functional with a 0.1  $\mu$ F capacitor value but is more sensitive to “pop and click” noises.

Thus, for optimized performances, a 1.0  $\mu$ F ceramic bypassing capacitor is recommended.

### Without Output Coupling Capacitor

As described in Figure 42, the internal circuitry of the NCP2809 device eliminates need of heavy bypassing capacitors when connecting a stereo headset with 3 connecting points. This circuitry produces a virtual ground and does not affect either output power or PSRR. Additionally, eliminating these capacitors reduces cost and PCB place.

However, user must take care to the connection between pin REF\_I and ground of the headset: this pin is the ground reference for the headset. **So, in order to improve crosstalk performances, this pin must be plugged directly to the middle point of the headset connector.**

### With Output Coupling Capacitor

However, when using a low cost jack connector (with third connection to ground), the headset amplifier requires very few external components as described in Figure 43. Only two external coupling capacitors are needed. The main concern is in output coupling capacitors, because of the value and consequently the size of the components required. Purpose of these capacitors is biasing DC voltage and very low frequency elimination. Both, coupling capacitor and output load form a high pass filter. Audible frequency ranges from 20 Hz to 20 kHz, but headset used in portable appliance has poor ability to reproduce signals below 75 or 100 Hz. Input coupling capacitor and input resistance also form a high pass filter. These two first order filters form a second order high pass filter with the same -3 dB cut off frequency. Consequently, the below formula must be followed:

$$\frac{1}{2 \times \pi \times R_{in} \times C_{in}} \approx \frac{1}{2 \times \pi \times R_L \times C_{out}} \quad (\text{eq. 2})$$

As for a loudspeaker amplifier, the input impedance value for calculating filters cut off frequency is the minimum input impedance value at maximum output volume.

To obtain a frequency equal to when frequency is 5 times the cut off frequency, attenuation is 0.5 dB. So if we want a  $\pm 0.5$  dB at 150 Hz, we need to have a -3 dB cut off frequency of 30 Hz:

$$f_{-3dB} \geq \frac{1}{2 \times \pi \times R_L \times C_{out}} \quad (\text{eq. 3})$$

$$C_{out} \geq \frac{1}{2 \times \pi \times R_L \times f_{-3dB}} \quad (\text{eq. 4})$$

With  $R_L = 16 \Omega$ , and  $f_{-3dB} = 30$  Hz formula (4) shows that  $C_{out} \geq 330 \mu$ F.

With  $C_{out} = 220 \mu$ F,  $\pm 0.5$  dB attenuation frequency will be 225 Hz with a -3.0 dB cut off frequency of 45 Hz. Following this, the input coupling capacitor choice is straightforward. Using formula (2) input coupling capacitor value would be 68 nF for a 220  $\mu$ F output coupling capacitor and 100 nF for a 330  $\mu$ F output coupling capacitor.

When using the NCP2809 with this configuration, pins REF\_I and OUT\_I must be left unconnected (see Figure 43).

### Optimum Equivalent Capacitance at Output Stage

Cellular phone and wireless portable device designers normally place several Radio Frequency filtering capacitors and ESD protection devices between the outputs and the headset connector. Those devices are usually connected between amplifier outputs and ground, or amplifier output and virtual ground. Different headsets with different impedance can be used with NCP2809. 16, 32 and 64Ohm are standard values. The extra impedance resulting of parasitic headset inductance and protections capacitance can affect sound quality.

In order to achieve the best sound quality, we suggest the optimum value of total equivalent capacitance:

- Between each output terminal to the virtual ground should be less than or equal to 100pF
- Between each output terminal to the ground should be less than or equal to 100pF.

This total equivalent capacitance consists of the radio frequency filtering capacitors and ESD protection device equivalent parasitic capacitance. Because of their very low parasitic capacitance value, diode based ESD protection are preferred.

If for some reason the above requirements cannot be met, a series resistor between each NCP2809 output and the protection device can improve amplifier operation. In order to keep dynamic output signal range, the resistor value should be very small compared to the loudspeaker impedance. For example, a 10Ohm resistor for a 64Ohm loudspeaker allows up to 400pF parasitic capacitance load.

### PCB LAYOUT GUIDELINES

#### How to Optimize the Accuracy of VMC

The main innovation of the NCP2809 stereo NOCAP audio amplifier is the use of a virtual ground that allows connecting directly the headset on the outputs of the device saving DC–blocking output capacitors. In order to have the best performances in terms of crosstalk, noise and supply current, the feedback connection on the virtual ground amplifier is not closed internally. To reach this goal of excellence, one must connect OUT\_I and REF\_I as close as possible from the middle point of the output jack connector. The most suitable place for this connection is directly on the pad of this middle point.

#### How to Optimize THD+N Performances

To get the best THD+N level on the headset speakers, the traces of the power supply, ground, OUT\_R, OUT\_L and OUT\_I need the lowest resistance. Thus, the PCB traces for these nets should be as wide and short as possible.

You need to avoid ground loops, run digital and analog traces parallel to each other. Due to its internal structure, the amplifier can be sensitive to coupling capacitors between Ground and each output (OUT\_R, OUT\_L and OUT\_I). Avoid running the output traces between two ground layers or if traces must cross over on different layers, do it at 90 degrees.
