Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Applications Information

Negative-Going V_{CC} Transients

In addition to issuing a reset to the microprocessor (μ P) during power-up, power-down, and brownout conditions, the MAX709 is relatively immune to short duration negative-going V_{CC} transients (glitches).

Figure 1 shows typical transient duration vs. reset comparator overdrive, for which the MAX709 does not generate a reset pulse. The graph was generated using a negative-going pulse applied to V_{CC}, starting 1.5V above the actual reset threshold and ending below it by the magnitude indicated (reset comparator overdrive). The graph indicates the typical maximum pulse width that a negative-going V_{CC} transient may have without causing a reset pulse to be issued. As the magnitude of the transient increases (goes farther below the reset threshold), the maximum allowable pulse width decreases. Typically, for the MAX709L/MAX709M, a V_{CC} transient that goes 100mV below the reset threshold and lasts 40 μ s or less will not cause a reset pulse to be issued.

Figure 1. Maximum Transient Duration without Causing a Reset Pulse vs. Reset Comparator Overdrive

A 0.1 μ F bypass capacitor mounted as close as possible to pin 2 (V_{CC}) provides additional transient immunity.

Ensuring a Valid RESET Output Down to V_{CC} = 0V

When V_{CC} falls below 1V, the MAX709 RESET output no longer sinks current—it becomes an open circuit. Therefore, high-impedance CMOS logic inputs connected to the RESET output can drift to undetermined voltages. This presents no problem in most applications, since most μ P and other circuitry is inoperative with V_{CC} below 1V. However, in applications where the RESET output must be valid down to 0V, adding a pull-down resistor to the RESET pin will cause any stray leakage currents to flow to ground, holding RESET low (see Figure 2). The resistance value of R1 is not critical. It should be about 100k Ω , which is large enough not to load RESET and small enough to pull RESET to ground.

MAX709

Interfacing to μPs with Bidirectional Reset Pins

Microprocessors with bidirectional reset pins (such as the Motorola 68HC11 series) can contend with the MAX709 RESET output. If, for example the MAX709 RESET output is asserted high and the μP wants to pull it low, indeterminate logic levels may result. To correct this, connect a $4.7\text{k}\Omega$ resistor between the MAX709 RESET output and the μP reset I/O (see Figure 3). Buffer the MAX709 RESET output to other system components.
