—	—	—	14	12	FORCEON	Force-On Input, Active High. Drive high to override AutoShutdown Plus, keeping transmitters and receivers on ($\overline{FORCEOFF}$ must be high) (Table 1).
—	—	—	20	16	$\overline{FORCEOFF}$	Force-Off Input, Active Low. Drive low to shut down transmitters, receivers, and charge pump. This overrides AutoShutdown Plus and FORCEON (Table 1).

Detailed Description

Dual Charge-Pump Voltage Converter

The MAX3316–MAX3319s' internal power supply consists of a regulated dual charge pump that provides output voltages of +4.4V (doubling charge pump) and -4.3V (inverting charge pump), over the +2.25V to +3.0V input voltage range. The charge pump operates in discontinuous mode: if the output voltages are less than 4.4V, the charge pump is enabled; if the output voltages exceed 4.4V, the charge pump is disabled. Each charge pump requires a flying capacitor (C1, C2) and a reservoir capacitor (C3, C4) to generate the V+ and V- supplies.

The READY output (MAX3318/MAX3319) is low when the charge pumps are disabled in shutdown mode. The READY signal asserts high when V- goes below -2.75V.

RS-232-Compatible Transmitters

The MAX3316–MAX3319s' transmitters are inverting level translators that convert CMOS-logic levels to RS-232-compatible voltage levels. They guarantee a 460kbps data rate with worst-case loads of 3kΩ in parallel with 1000pF, providing compatibility with PC-to-PC communication software (such as LapLink™).

The MAX3317's transmitters are turned off (high impedance) when $\overline{SHDN}$ is asserted low, putting the device in shutdown mode. The MAX3318/MAX3319s' transmitters are turned off (high impedance) when $\overline{FORCEOFF}$ is asserted low, or when the AutoShutdown Plus circuitry senses that all receiver and transmitter inputs are inactive for more than 30 seconds.

The transmitter outputs can be driven to ±12V when power is off. The transmitter inputs do not have internal pullup resistors. Connect unused inputs to GND or V_{CC}.

Figure 1a shows an RS-232-compatibility circuit and Figure 1b shows MAX3316–MAX3319 transmitter output compatibility with an RS-232 receiver.

RS-232 Receivers

The MAX3316–MAX3319s' receivers convert RS-232 signal levels into CMOS-logic output levels. The receivers are rated to receive signals up to ±25V. The MAX3316/MAX3318/MAX3319s' receivers feature inverting outputs that always remain active (Table 1). The MAX3317's receivers have inverting, three-state outputs. In shutdown, the receivers can be active or inactive (Table 2).

The MAX3318/MAX3319 feature an $\overline{INVALID}$ output that is asserted low when no valid RS-232 voltage levels have been detected on all receiver inputs. Because $\overline{INVALID}$ indicates the receiver's input condition, it is independent of the states of FORCEON and $\overline{FORCEOFF}$.

LapLink is a trademark of Traveling Software.

$\overline{\text{SHDN}}$	$\overline{\text{EN}}$	T_OUT	R_OUT
0	0	High-Z	Active
0	1	High-Z	High-Z
1	0	Active	Active
1	1	Active	High-Z

MAX3317 Shutdown Mode

Supply current falls to less than 1µA in shutdown mode ($\overline{\text{SHDN}}$ = low). When shut down, the device's charge pumps are turned off, V+ is pulled down to V_{CC}, V- is pulled to ground, and the transmitter outputs are disabled (high impedance). The time required to exit shutdown is typically 30µs, as shown in Figure 2. Connect $\overline{\text{SHDN}}$ to V_{CC} if the shutdown mode is not used; $\overline{\text{SHDN}}$ has no effect on R_OUT.

MAX3318/MAX3319 AutoShutdown Plus Mode

Maxim's AutoShutdown Plus feature on the MAX3318/MAX3319 allows the supply current to fall to 1µA. These devices will enter the AutoShutdown Plus mode if $\overline{\text{FORCEOFF}}$ is high, FORCEON is low, and they do not sense a valid signal transition on any receiver or transmitter input for 30 seconds. This may occur if the RS-232 cable is disconnected or if the peripheral transmitters are turned off, and the UART driving the transmitter inputs is inactive. The system turns on again when a valid transition is applied to any RS-232 receiver or transmitter input. As a result, the system saves power without changes to the existing BIOS or operating system.

Figure 4a depicts valid and invalid RS-232 receiver voltage levels. $\overline{\text{INVALID}}$ indicates the receiver input's condition and is independent of FORCEON and $\overline{\text{FORCEOFF}}$ states. Figure 3 and Table 1 summarize the operating modes of the MAX3318/MAX3319. FORCEON and $\overline{\text{FORCEOFF}}$ override AutoShutdown Plus circuitry. When neither control is asserted, the IC selects between these states automatically, based on the last receiver or transmitter edge received.

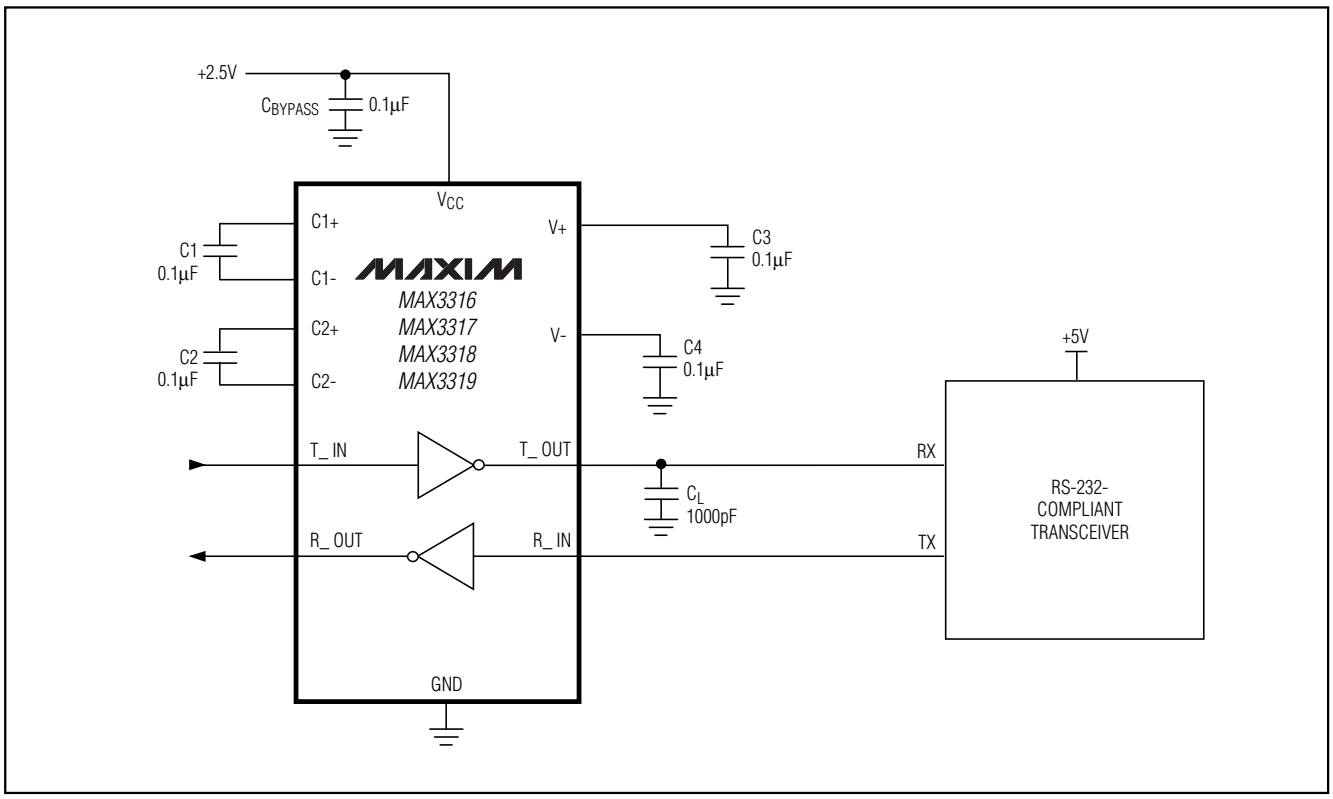

Figure 1a. RS-232-Compatibility Circuit

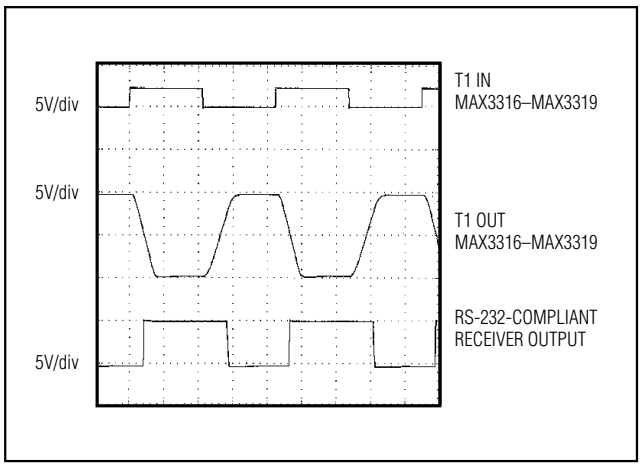

Figure 1b. MAX3316–MAX3319 Transmitter Output Compatibility with an RS-232 Receiver

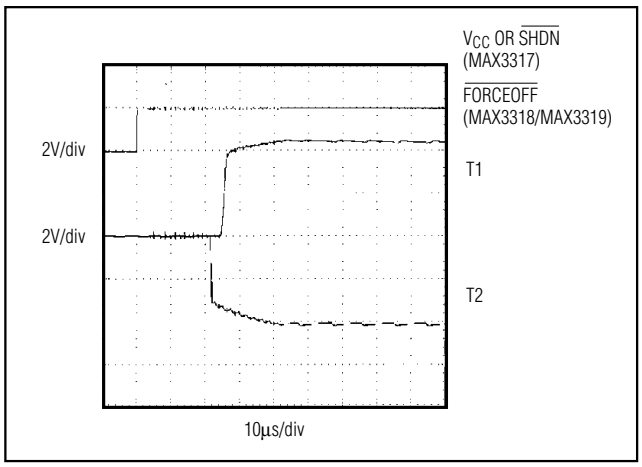

Figure 2. Transmitter Outputs when Exiting Shutdown or Powering Up

2.5V, 1µA, 460kbps, RS-232-Compatible Transceivers

When shut down, the device's charge pumps turn off, V+ is pulled to V_{CC}, V- is pulled to ground, the transmitter outputs are high impedance, and READY is driven low. The time required to exit shutdown is typically 30µs (Figure 2).

By connecting FORCEON to $\overline{\text{INVALID}}$, the MAX3318/MAX3319 shut down when no valid receiver level is detected and wake up when a valid receiver level is detected.

A system with AutoShutdown Plus may need time to wake up. Figure 5 shows a circuit that forces the transmitters on for 100ms, allowing enough time for the other system to realize that the MAX3318/MAX3319 is awake. If the other system outputs valid RS-232 signal transitions within that time, the RS-232 ports on both systems remain enabled.

Connecting to the PC (MAX3318/MAX3319)

If direct software control is desired, use $\overline{\text{INVALID}}$ to indicate DTR or ring indicator (RI) signal. This can be used to connect a hand-held device to a PC. One example is using the hot sync function on a personal digital assistant (PDA). The transmitter and receiver signals (T_OUT and R_IN) are used for communication, while $\overline{\text{INVALID}}$ causes a change of state on RI. The change of state on RI will trigger an interrupt on the PC and allow communication to begin between the device and the PC. This eliminates the need for the PC to poll constantly the receiver or transmitter lines to determine if the device is connected.

Applications Information

RS-232-Compatible Operation

The MAX3316–MAX3319 do not meet EIA-232 requirements for transmitter output voltage levels. EIA-232 compliance specifies transmitter output voltage swings of ±5V when loaded with 3kΩ and 2500pF.

The receiver inputs are fully EIA-232 compliant.

The MAX3316–MAX3319 will function properly with most modern RS-232 interfaces. This allows RS-232-compatible communication in low-voltage systems without the added expense of a voltage tripler or switched-mode power supply.

Capacitor Selection

The capacitor type used for C1–C4 is not critical for proper operation; polarized or nonpolarized capacitors can be used. The charge pump requires 0.1µF capacitors. Increasing the capacitor values (e.g., by a factor of 2) reduces ripple on the transmitter outputs and slightly reduces power consumption. C2, C3, and C4 can be increased without changing C1's value. **However, do not increase C1 without also increasing the values of**

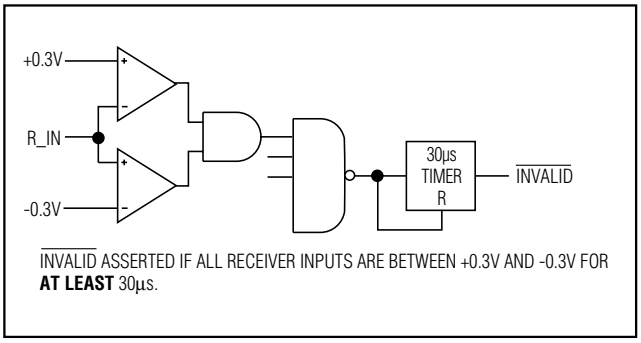

Figure 3a. $\overline{\text{INVALID}}$ Functional Diagram, $\overline{\text{INVALID}}$ Low

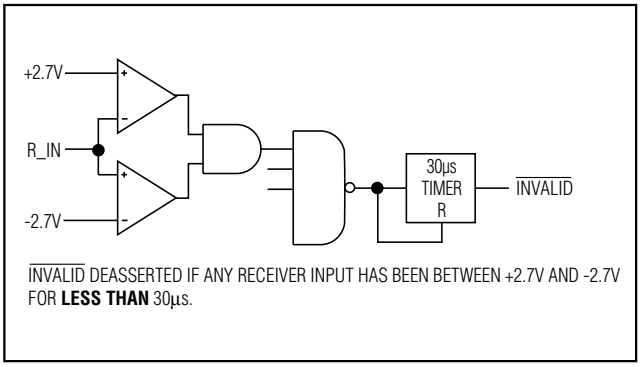

Figure 3b. $\overline{\text{INVALID}}$ Functional Diagram, $\overline{\text{INVALID}}$ High

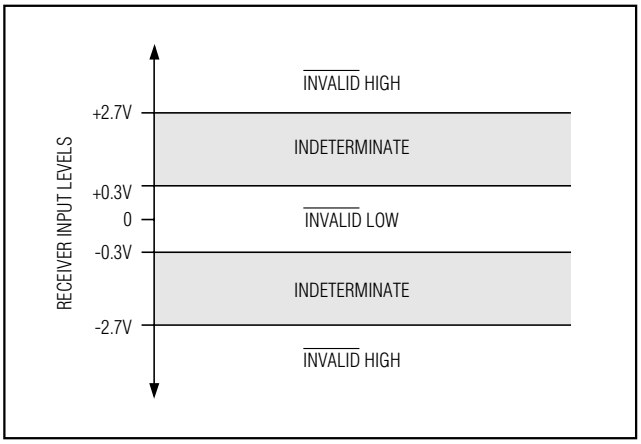

Figure 4a. Receiver Positive/Negative Thresholds for $\overline{\text{INVALID}}$

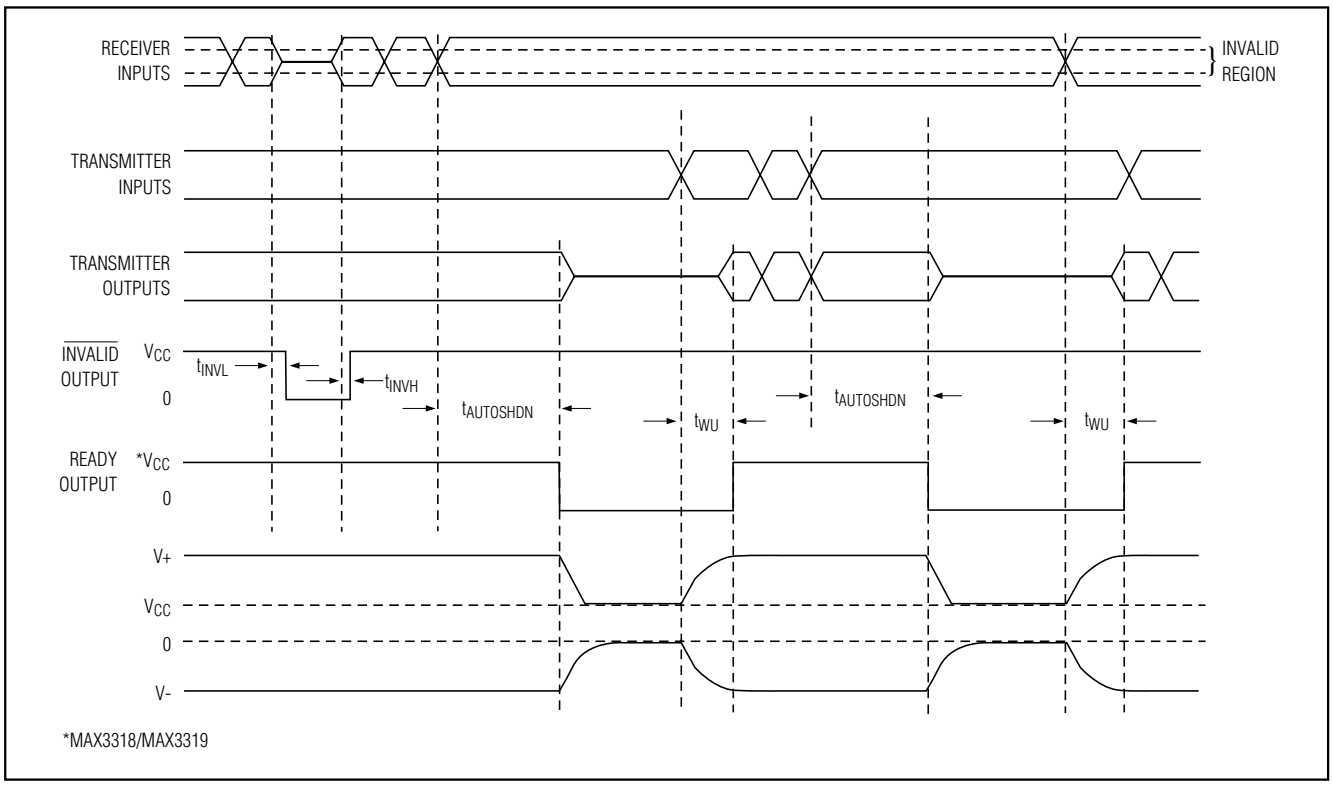

Figure 4b. AutoShutdown Plus, $\overline{INVALID}$, and READY Timing Diagram

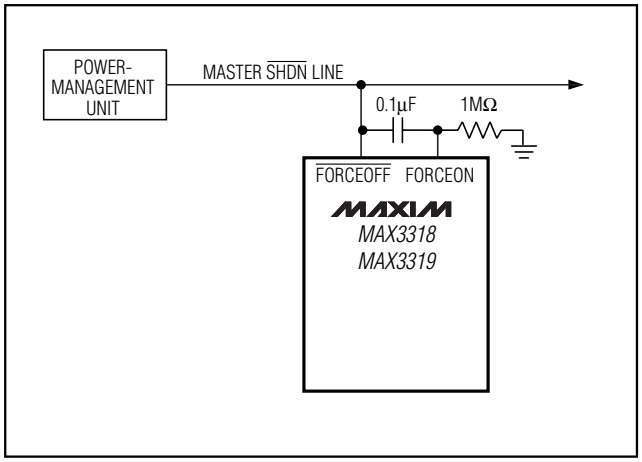

Figure 5. AutoShutdown Plus Initial Turn-On to Wake Up a Mouse or Another System

C2, C3, C4, and C_{BYPASS} to maintain proper ratios (C1 to other capacitors).

When using the minimum-required capacitor values, make sure the capacitor value does not degrade excessively with temperature. If in doubt, use capacitors with a higher nominal value. The capacitor's equivalent series resistance (ESR), which usually rises at low temperatures, influences the amount of ripple on V+ and V-.

Power-Supply Decoupling

In most circumstances, a 0.1µF bypass capacitor is adequate. In applications that are sensitive to power-supply noise, decouple V_{CC} to ground with a capacitor of the same value as charge pump capacitor C1. Connect bypass capacitors as close to the IC as possible.

Transmitter Outputs when Exiting Shutdown

Figure 2 shows two transmitter outputs when exiting shutdown mode. As they become active, the two transmitter outputs are shown going to opposite RS-232-compatible levels (one transmitter input is high, the other is low). Each transmitter is loaded with 3kΩ in par-

2.5V, 1µA, 460kbps, RS-232-Compatible Transceivers

allel with 2500pF. The transmitter outputs display no ringing or undesirable transients as they come out of shutdown. Note that the transmitters are enabled only when the magnitude of V- exceeds approximately -3V.

High Data Rates

The MAX3316–MAX3319 maintain RS-232-compatible ±3.7V minimum transmitter output voltage even at high data rates. Figure 6 shows a transmitter loopback test circuit. Figure 7 shows a loopback test result at 230kbps. For Figure 7, all transmitters were driven simultaneously at 230kbps into EIA/TIA-562 loads in parallel with 1000pF.
