ABSOLUTE MAXIMUM RATINGS

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

 $(V+= +5V \pm 5\%$, $V_{DD} = +2.7V$ to $+5.25V$, $V_{REFIN+} = +2.50V$, REFIN- = AGND, $f_{CLKIN} = 2.4576$ MHz, TA = TMIN to TMAX, unless otherwise noted. Typical values are at $T_A = +25^{\circ}C$.)

ELECTRICAL CHARACTERISTICS (continued)

 $(V_{+} = +5V \pm 5\%$, $V_{DD} = +2.7V$ to $+5.25V$, $V_{REFIN_{+}} = +2.50V$, REFIN- = AGND, $f_{CLKIN} = 2.4576MHz$, $T_A = T_{MIN}$ to T_{MAX} , unless otherwise noted. Typical values are at $T_A = +25^{\circ}C$.)

ELECTRICAL CHARACTERISTICS (continued)

(V+ = +5V ±5%, VDD = +2.7V to +5.25V, VREFIN+ = +2.50V, REFIN- = AGND, fCLKIN = 2.4576MHz, TA = TMIN to TMAX, unless otherwise noted. Typical values are at $TA = +25^{\circ}C$.)

ELECTRICAL CHARACTERISTICS (continued)

 $(V_{+} = +5V \pm 5\%$, $V_{DD} = +2.7V$ to $+5.25V$, $V_{REFIN_{+}} = +2.50V$, REFIN- = AGND, $f_{CLKIN} = 2.4576MHz$, $T_A = T_{MIN}$ to T_{MAX} , unless otherwise noted. Typical values are at $T_A = +25^{\circ}C$.)

ELECTRICAL CHARACTERISTICS (continued)

 $(V_{+} = +5V \pm 5\%$, $V_{DD} = +2.7V$ to $+5.25V$, $V_{REFIN+} = +2.50V$, REFIN- = AGND, $f_{CLKIN} = 2.4576MHz$, $T_A = T_{MIN}$ to T_{MAX} , unless otherwise noted. Typical values are at $TA = +25^{\circ}C$.)

- **Note 1:** Nominal gain is 0.98. This ensures a full-scale input voltage may be applied to the part under all conditions without causing saturation of the digital output data.
- **Note 2:** Positive Full-Scale Error includes zero-scale errors (unipolar offset error or bipolar zero error) and applies to both unipolar and bipolar input ranges. This error does not include the nominal gain of 0.98.
- **Note 3:** Full-Scale Drift includes zero-scale drift (unipolar offset drift or bipolar zero drift) and applies to both unipolar and bipolar input ranges.
- **Note 4:** Gain Error does not include zero-scale errors. It is calculated as (full-scale error unipolar offset error) for unipolar ranges and as (full-scale error - bipolar zero error) for bipolar ranges. This error does not include the nominal gain of 0.98.
- **Note 5:** Gain-Error Drift does not include unipolar offset drift or bipolar zero drift. It is effectively the drift of the part if zero-scale error is removed.
- **Note 6:** Use of the offset DAC does not imply that any input may be taken below AGND.
- **Note 7:** Additional noise added by the offset DAC is dependent on the filter cutoff, gain, and DAC setting. No noise is added for a DAC code of 0000.
- **Note 8:** Guaranteed by design or characterization; not production tested.
- **Note 9:** The input voltage must be within the Absolute Input Voltage Range specification.
- **Note 10:** All AIN and REFIN pins have identical input structures. Leakage is production tested only for the AIN3, AIN4, AIN5, CALGAIN, and CALOFF inputs.
- **Note 11:** The dynamic load presented by the MAX1400 analog inputs for each gain setting is discussed in detail in the *Switching Network* section*.* Values are provided for the maximum allowable external series resistance. Note that this value does not include any additional capacitance added by the user to the MUXOUT_ or ADCIN_ pins.
- **Note 12:** The input voltage range for the analog inputs is with respect to the voltage on the negative input of its respective differential or pseudo-differential pair. Table 5 shows which inputs form differential pairs.

```
Note 13: V_{REF} = V_{REFIN+} - V_{REFIN-}.
```
- **Note 14:** These specifications apply to CLKOUT only when driving a single CMOS load.
- **Note 15:** The burn-out currents require a 500mV overhead between the analog input voltage and both V+ and AGND to operate correctly.

6 ___

- **Note 16:** Measured at DC in the selected passband. PSR at 50Hz will exceed 120dB with filter notches of 25Hz or 50Hz and FAST bit = 0. PSR at 60Hz exceeds 120dB with filter notches of 20Hz or 60Hz and FAST bit = 0.
- Note 17: PSR depends on gain. For a gain of +1V/V, PSR is 70dB typical. For a gain of +2V/V, PSR is 75dB typical. For a gain of +4V/V, PSR is 80dB typical. For gains of +8V/V to +128V/V, PSR is 85dB typical.
- **Note 18:** Standby power-dissipation and current specifications are valid only with CLKIN driven by an external clock and with the external clock stopped. If the clock continues to run in standby mode, the power dissipation will be considerably higher. When used with a resonator or crystal between CLKIN and CLKOUT, the actual power dissipation and I_{DD} in standby mode depends on the resonator or crystal type.

TIMING CHARACTERISTICS

 $(V_+ = +5V \pm 5\%$, $V_{DD} = +2.7V$ to +5.25V, AGND = DGND, $f_{CLKIN} = 2.4576$ MHz; input logic 0 = 0V; logic 1 = V_{DD}, T_A = T_{MIN} to T_{MAX}, unless otherwise noted.) (Notes 19, 20, 21)

TIMING CHARACTERISTICS (continued)

 $(V+= +5V \pm 5\%$, $V_{DD} = +2.7V$ to $+5.25V$, AGND = DGND, $f_{CLKIN} = 2.4576MHz$; input logic 0 = 0V; logic 1 = V_{DD}, T_A = T_{MIN} to T_{MAX}, unless otherwise noted.) (Notes 19, 20, 21)

Note 19: All input signals are specified with $t_r = t_f = 5$ ns (10% to 90% of V_{DD}).

Note 20: See Figure 4.

- **Note 21:** Timings shown in tables are for the case where SCLK idles high between accesses. The part may also be used with the SCLK idling low between accesses, provided \overline{CS} is toggled. In this case SCLK in the timing diagrams should be inverted and the terms "SCLK Falling Edge" and "SCLK Rising Edge" exchanged in the specification tables. If \overline{CS} is permanently tied low, the part should only be operated with SCLK idling high between accesses.
- **Note 22:** CLKIN duty cycle range is 45% to 55%. CLKIN must be supplied whenever the MAX1400 is not in standby mode. If no clock is present, the device can draw higher current than specified.
- **Note 23:** The MAX1400 is production tested with f_{CLKIN} at 2.5MHz (1MHz for some I_{DD} tests).
- **Note 24:** Measured with the load circuit of Figure 1 and defined as the time required for the output to cross the VOL or VOH limits. **Note 25:** For read operations, SCLK active edge is falling edge of SCLK.
- **Note 26:** Derived from the time taken by the data output to change 0.5V when loaded with the circuit of Figure 1. The number is then extrapolated back to remove effects of charging or discharging the 50pF capacitor. This ensures that the times quoted in the timing characteristics are true bus-relinquish times and are independent of external bus loading capacitances.
- **Note 27:** INT returns high after the first read after an output update. The same data can be read again while INT is high, but be careful not to allow subsequent reads to occur close to the next output update.

Pin Description

Pin Description (continued)

MAXIM

_______________Detailed Description

Circuit Description

The MAX1400 is a low-power, multichannel, serialoutput, sigma-delta ADC designed for applications with a wide dynamic range, such as weigh scales and pressure transducers. The functional block diagram in Figure 2 contains a switching network, a modulator, a PGA, two buffers, an oscillator, an on-chip digital filter, and a bidirectional serial communications port.

Three fully-differential input channels feed into the switching network. Each channel may be independently programmed with a gain between +1V/V and +128V/V. These three differential channels may also be configured to operate as five pseudo-differential input channels. Two additional, fully differential system-calibration channels allow system gain and offset error to be measured. These system-calibration channels can be used as additional differential signal channels when dedicated gain and offset error correction channels are not required.

Two chopper-stabilized buffers are available to isolate the selected inputs from the capacitive loading of the PGA and modulator. Three independent DACs provide compensation for the DC component of the input signal on each of the differential input channels.

The sigma-delta modulator converts the input signal into a digital pulse train whose average duty cycle represents the digitized signal information. The pulse train is then processed by a digital decimation filter, resulting in a conversion accuracy exceeding 16 bits. The digital filter's decimation factor is user-selectable, which allows the conversion result's resolution to be reduced to achieve a higher output data rate. When used with 2.4576MHz or 1.024MHz master clocks, the decimation filter can be programmed to produce zeros in its frequency response at the line frequency and associated harmonics. This ensures excellent line rejection without the need for further post-filtering. In addition, the modulator sampling frequency can be optimized for either lowest power dissipation or highest output data rate.

The MAX1400 can be configured to sequentially scan all signal inputs and to transmit the results through the serial interface with minimum communications overhead. The output word contains a result identification tag to indicate the source of each conversion result.

Figure 2. Functional Diagram

Serial Digital Interface

The serial digital interface provides access to eight onchip registers (Figure 3). All serial-interface commands begin with a write to the communications register (COMM). On power-up, system reset, or interface reset, the part expects a write to its communications register. The COMM register access begins with a 0 start bit. The COMM register R/\overline{W} bit selects a read or write operation, and the register select bits (RS2, RS1, RS0) select the register to be addressed. Hold DIN high when not writing to COMM or another register (Table 1).

The serial interface consists of five signals: \overline{CS} , SCLK, DIN, DOUT, and INT. Clock pulses on SCLK shift bits into DIN and out of DOUT. INT provides an indication that data is available. CS is a device chip-select input as well as a clock polarity select input (Figure 4).

Using \overline{CS} allows the SCLK, DIN, and DOUT signals to be shared among several SPI-compatible devices. When short on I/O pins, connect \overline{CS} low and operate the serial digital interface in $CPOL = 1$, $CPHA = 1$ mode using SCLK, DIN, and DOUT. This 3-wire interface mode is ideal for opto-isolated applications. Furthermore, a microcontroller (such as a PIC16C54 or 80C51) can use a single bidirectional I/O pin for both sending to DIN and receiving from DOUT (see *Applications Information*), because the MAX1400 drives DOUT only during a read cycle.

Additionally, connecting the INT signal to a hardware interrupt allows faster throughput and reliable, collisionfree data flow.

The MAX1400 features a mode where the raw modulator data output is accessible. In this mode the DOUT and INT functions are reassigned (see the *Modulator Data Output* section).

Figure 3. Register Summary

Figure 4. Serial-Interface Timing

Selecting Clock Polarity

The serial interface can be operated with the clock idling either high or low. This is compatible with Motorola's SPI interface operated in (CPOL = 1, CPHA $= 1$) or (CPOL $= 0$, CPHA $= 1$) mode. Select the clock polarity by sampling the state of SCLK at the falling edge of \overline{CS} . Ensure that the setup times t₄/t₁₂ and t₅/t₁₃ are not violated. If \overline{CS} is connected to ground, resulting in no falling edge on \overline{CS} , SCLK must idle high (CPOL = 1, CPHA $= 1$).

Data-Ready Signal (DRDY bit true or INT *= low)*

The data-ready signal indicates that new data may be read from the 24-bit data register. After the end of a successful data register read, the data-ready signal becomes false. If a new measurement completes before the data is read, the data-ready signal becomes false. The data-ready signal becomes true again when new data is available in the data register.

The MAX1400 provides two methods of monitoring the data-ready signal. INT provides a hardware solution (active low when data is ready to be accessed), while the DRDY bit in the COMM register provides a software solution (active high).

Read data as soon as possible once data-ready becomes true. This becomes increasingly important for faster measurement rates. If the data-read is delayed significantly, a collision may result. A collision occurs when a new measurement completes during a dataregister read operation. After a collision, information in the data register is invalid. The failed read operation must be completed even though the data is invalid.

Resetting the Interface

Reset the serial interface by clocking in 32 1s. Resetting the interface does not affect the internal registers.

If continuous data output mode is in use, clock in eight 0s followed by 32 1s. More than 32 1s may be clocked in, since a leading 0 is used as the start bit for all operations.

Continuous Data Output Mode

When scanning the input channels ($SCAN = 1$), the serial interface allows the data register to be read repeatedly without requiring a write to the COMM register. The initial COMM write (01111000) is followed by 24 clocks ($DIN = high$) to read the 24-bit data register. Once the data register has been read, it can be read again after the next conversion by writing another 24 clocks (DIN = high). Terminate the continuous data output mode by writing to the COMM register with any valid access.

Modulator Data Output (MDOUT = 1)

Single-bit, raw modulator data is available at DOUT for custom filtering when MDOUT = $1. \overline{INT}$ provides a modulator clock for data synchronization. Data is valid on the falling edge of INT. Write operations can still be performed, however, read operations are disabled. After MDOUT is returned to 0, valid data is accessed by the normal serial-interface read operation.

On-Chip Registers

Communications Register

0/DRDY: (Default = 0) Data Ready Bit. On a write, this bit must be reset to 0 to signal the start of the Communications Register data word. On a read, a 1 in this location (0/DRDY) signifies that valid data is available in the data register. This bit is reset after the data register is read or, if data is not read, 0/DRDY will go low at the end of the next measurement.

RS2, RS1, RS0: (Default = 0, 0, 0) Register Select Bits. These bits select the register to be accessed (Table 1).

R/W**:** (Default = 0) Read/Write Bit. When set high, the selected register is read; when $R/\overline{W} = 0$, the selected register is written.

RESET: (Default = 0) Software Reset Bit. Setting this bit high causes the part to be reset to its default powerup condition ($REST = 0$).

STDBY: (Default = 0) Standby Power-Down Bit. Setting the STDBY bit places the part in "standby" condition, shutting down everything except the serial interface and the CLK oscillator.

Communications Register

First Bit (MSB) (LSB) FUNCTION $\overline{0}$ **STDBY** Ω RESET Ω Name FSYNC Ω **REGISTER SELECT BITS** RS0 $\overline{0}$ RS1 $\overline{0}$ **DATA RDY Defaults** RS2 0 0 0 0 0 0 0/DRDY | RS2 | RS1 | RS0 | R/W

MAX1400 **MAX1400**

+5V, 18-Bit, Low-Power, Multichannel, Oversampling (Sigma-Delta) ADC

FSYNC: (Default = 0) Filter Sync Bit. When $FSYNC = 0$, conversions are automatically performed at a data rate determined by CLK, FS1, FS0, MF1, and MF0 bits. When FSYNC = 1, the digital filter and analog modulator are held in reset, inhibiting normal self-timed operation. This bit may be used to convert on command to minimize the settling time to valid output data, or to synchronize operation of a number of MAX1400s. FSYNC does not reset the serial interface or the 0/DRDY flag. To clear the 0/DRDY flag while FSYNC is active, simply read the data register.

Global Setup Register 1

A1, A0: (Default = 0, 0) Channel-Selection Control Bits. These bits (combined with the state of the DIFF, M1, and M0 bits) determine the channel selected for conversion according to Tables 8, 9, and 10. These bits are ignored if the SCAN bit is set.

MF1, MF0: (Default = 0, 0) Modulator Frequency Bits. MF1 and MF0 determine the ratio of CLKIN oscillator frequency to modulator operating frequency. They affect the output data rate, the position of the digital filter notch frequencies, and the power dissipation of the device. Achieve lowest power dissipation with $MFI = 0$ and MFO = 0. Highest power dissipation and fastest output data rate occur with these bits set to 1, 1 (Table 2).

CLK: (Default = 1) CLK Bit. The CLK bit is used in conjunction with X2CLK to tell the MAX1400 the frequency of the CLKIN input signal. If $CLK = 0$, a $CLKIN$ input frequency of 1.024MHz (2.048MHz for $X2CLK = 1$) is expected. If $CLK = 1$, a $CLKIN$ input frequency of 2.4576MHz $(4.1952$ MHz for X2CLK = 1) is expected. This bit affects the decimation factor in the digital filter and thus the output data rate (Table 2).

FS1, FS0: (Default = 0, 1) Filter Selection Bits. These bits (in conjunction with the CLK bit) control the decimation ratio of the digital filter. They determine the out-

put data rate, the position of the digital filter-frequency response notches, and the noise present in the output result. (Table 2).

FAST: (Default 0) FAST Bit. FAST = 0 causes the digital filter to perform a $SINC³$ filter function on the modulator data stream. The output data rate will be determined by the values in the CLK, FS1, FS0, MF1, and MF0 bits (Table 2). The settling time for SINC³ function is 3 [1 / (output data rate)]. In SINC³ mode, the MAX1400 automatically holds the DRDY signal false (after any significant configuration change) until settled data is available. FAST $= 1$ causes the digital filter to perform a SINC¹ filter function on the modulator data stream. The signal-to-noise ratio achieved with this filter function is less than that of the $SINC³$ filter; however $SINC¹$ settles in a single output sample period, rather than a minimum of three output sample periods for $SINC³$. When switching from $SINC¹$ to $SINC³$ mode, the DRDY flag will be deasserted and reasserted after the filter has fully settled. This mode change requires a minimum of three samples.

Global Setup Register 2

SCAN: (Default = 0) Scan Bit. Setting this bit to a 1 causes sequential scanning of the input channels as determined by DIFF, M1, and M0 (see *Scanning* (*SCAN-mode*) section). When SCAN = 0, the MAX1400 repeatedly measures the unique channel selected by A1, A0, DIFF, M1, and M0.

M1, M0: (Default 0, 0) Mode Control Bits. These bits control access to the calibration channels CALOFF and CALGAIN. When $SCAN = 0$, setting $M1 = 0$ and $M0 = 1$ selects the CALOFF input, and $M1 = 1$ and $M0 = 0$ selects the CALGAIN input (Table 3). When $SCAN = 1$ and $M1 \neq MO$, the scanning sequence includes both CALOFF and CALGAIN inputs (Table 4). When SCAN is set to 1 and the device is scanning the available input

Global Setup Register 1

Global Setup Register 2

channels, selection of either calibration mode (01 or 10) will cause the scanning sequence to be extended to include a conversion on both the CALGAIN+/ CALGAIN- input pair and the CALOFF+/CALOFF- input pair. The exact sequence depends on the state of the DIFF bit (Table 4). When scanning, the calibration channels use the PGA gain, format, and DAC settings defined by the contents of Transfer Function Register 3.

BUFF: (Default = 0) The BUFF bit controls operation of the input buffer amplifiers. When this bit is 0, the internal buffers are bypassed and powered down. When this bit is set high, the buffers drive the input sampling capacitors and minimize the dynamic input load.

DIFF: (Default = 0) Differential/Pseudo-Differential Bit. When $DIFF = 0$, the part is in pseudo-differential mode, and AIN1–AIN5 are measured respective to AIN6, the analog common. When $DIF = 1$, the part is in differential mode with the analog inputs defined as AIN1/AIN2, AIN3/AIN4, and AIN5/AIN6. The available input channels for each mode are tabulated in Table 5. Note that DIFF also affects the scanning sequence when the part is placed in SCAN mode (Table 4).

BOUT: (Default = 0) Burnout Current Bit. Setting BOUT = 1 connects 100nA current sources to the selected analog input channel. This mode is used to check that a transducer has not burned out or opened circuit. The burnout current source must be turned off $(BOUT = 0)$ before measurement to ensure best linearity.

RESERVED: (Default = 0) Reserved Bit. A 0 must be written to this location.

X2CLK: (Default = 0) Times-Two Clock Bit. Setting this bit to 1 selects a divide-by-2 prescaler in the clock signal path. This allows use of a higher frequency crystal or clock source and improves immunity to asymmetric clock sources.

Table 2. Data Output Rate vs. CLK, Filter Select, and Modulator Frequency Bits

**Data rates offering noise-free 16-bit resolution.*

Note: When FAST = 0, f-3dB = 0.262 \times *Data Rate. When FAST = 1, f-3dB = 0.443* \times *Data Rate. Default condition is in bold print.*

Table 3. Special Modes Controlled by M1, M0 (SCAN = 0)

M1	MО	DESCRIPTION			
		Normal Mode: The device operates normally.			
		Calibrate Offset: In this mode the MAX1400 converts the voltage applied across CALOFF+ and CALOFF-. The PGA gain, DAC, and format settings of the selected channel (defined by DIFF, A1, A0) are used.			
		Calibrate Gain: In this mode the MAX1400 converts the voltage applied across CALGAIN+ and CALGAIN-. The PGA gain, DAC, and format settings of the selected channel (defined by DIFF, A1, A0) are used.			
		Reserved: Do not use.

Table 4. SCAN Mode Scanning Sequences (SCAN = 1)

Note: All other combinations reserved.

Table 5. Available Input Channels (SCAN = 0)

Special Function Register (Write-Only)

Transfer-Function Register

Special Function Register (Write-Only)

MDOUT: (Default = 0) Modulator Out Bit. MDOUT = 0 enables data readout on the DOUT pin, the normal condition for the serial interface. MDOUT $=$ 1 changes the function of the DOUT and INT pins, providing raw, single-bit modulator output instead of the normal serialdata interface output. This allows custom filtering directly on the modulator output, without going through the on-chip digital filter. The INT pin provides a clock to indicate when the modulator data at DOUT should be sampled (falling edge of $\overline{\text{INT}}$). Note that in this mode, the on-chip digital filter continues to operate normally. When MDOUT is returned to 0, valid data may be accessed through the normal serial-interface read operation.

FULLPD: (Default = 0) Complete Power-Down Bit. $FULLPD = 1$ forces the part into a complete powerdown condition, which includes the clock oscillator. The serial interface continues to operate. The part requires a hardware reset to recover correctly from this condition.

Note: Changing the reserved bits in the special-function register from the default status of all 0s will select one of the reserved modes and the part will not operate as expected. This register is a write-only register. However, in the event that this register is mistakenly read, clock 24 bits of data out of the part to restore it to the normal interface-idle state.

Transfer-Function Registers

The three transfer-function registers control the method used to map the input voltage to the output codes. All of the registers have the same format. The mapping of control registers to associated channels depends on the mode of operation and is affected by the state of M1, M0, DIFF, and SCAN (Tables 8, 9, and 10).

Analog Inputs AIN1 to AIN6

Inputs AIN1 and AIN2 map to transfer-function register 1, regardless of scanning mode ($SCAN = 1$) or singleended vs. differential (DIFF) modes. Likewise, AIN3 and AIN4 inputs always map to transfer-function register 2. Finally, AIN5 always maps to transfer-function register 3 (input AIN6 is analog common).

CALGAIN and CALOFF

When not in scan mode (SCAN $= 0$), A1 and A0 select which transfer function applies to CALGAIN and CALOFF. In scan mode (SCAN = 1), CALGAIN and CALOFF are always mapped to transfer-function register 3. Note that when scanning while M1 \neq M0, the scan sequence includes both CALGAIN and CALOFF channels (Table 4). CALOFF always precedes CALGAIN, even though both channels share the same channel ID tag (Table 11).

Note that changing the status of any **active** channel control bits will cause INT to immediately transition high and the modulator/filter to be reset. INT will reassert after the appropriate digital-filter settling time. The control settings of the inactive channels may be changed freely without affecting the status of INT or causing the filter/modulator to be reset.

PGA Gain

Bits G2–G0 control the PGA gain according to Table 6.

Unipolar/Bipolar Mode

The U/B bit places the channel in either bipolar or unipolar mode. A 0 selects bipolar mode, and a 1 selects unipolar mode. This bit does not affect the analog-signal conditioning. The modulator always accepts bipolar inputs and produces a bitstream with 50% ones-density when the selected inputs are at the same potential. This bit controls the processing of the digitalfilter output, such that the available output bits are

mapped to the correct output range. Note U/\overline{B} must be set before a conversion is performed; it will not affect any data already held in the output register.

Selecting bipolar mode does not imply that any input may be taken below AGND. It simply changes the gain and offset of the part. All inputs must remain within their specified operating voltage range.

Offset-Correction DACs

Bits D3–D0 control the offset-correction DAC. The DAC range depends on the PGA gain setting and is expressed as a percentage of the available full-scale input range (Table 7).

D3 is a sign bit, and D2–D0 represent the DAC magnitude. Note that when a DAC value of 0000 is programmed (the default), the DAC is disconnected from the modulator inputs. This prevents the DAC from degrading noise performance when offset correction is not required.

Transfer-Function Register Mapping

Tables 8, 9, and 10 show the channel-control register mapping in the various operating modes.

Table 7. DAC Code vs. DAC Value

Table 8. Transfer-Function Register Mapping—Normal Mode (M1 = 0, M0 = 0)

X = Don't Care.

Table 9. Transfer-Function Register Mapping—Offset-Cal Mode (M1 = 0, M0 = 1)

MAXIM

X = Don't Care.

Data Register (Read-Only)

The data register is a 24-bit, read-only register. Any attempt to write data to this location will have no effect. If a write operation is attempted, 8 bits of data must be clocked into the part before it will return to its normal idle mode, expecting a write to the communications register.

Data is output MSB first, followed by three reserved 0 bits and a 3-bit channel ID tag indicating the channel from which the data originated.

D17–D0: The conversion result. D17 is the MSB. The result is in offset binary format. 00 0000 0000 0000 0000 represents the minimum value and 11 1111 1111 1111 1111 represents the maximum value. Inputs exceeding the available input range are limited to the corresponding minimum or maximum output values.

0: These reserved bits will always be 0.

CID2–0: Channel ID tag (Table 11).

Data Register (Read-Only) Bits

Switching Network

CID2 CHANNEL 1 1 AIN1–AIN2 AIN5–AIN6 1 | 1 | 1 | Calibration 1 0 1 0 1 AIN3–AIN4 0 0 0 $\overline{0}$ AIN1–AIN6 AIN3–AIN6 0 1 1 1 AIN4–AIN6 1 0 0 0 0 1 1 AIN2–AIN6 **CID0** 0 **CID1** 0

A switching network provides selection between three fully differential input channels or five pseudo-differential channels, using AIN6 as a shared common. The switching network provides two additional fully differential input channels intended for system calibration, which may be used as extra fully differential signal channels. Table 12 shows the channel configurations

available for both operating modes.

Table 11. Channel ID Tag Codes

Scanning (SCAN-mode)

To sample and convert the available input channels sequentially, set the SCAN control bit in the global setup register. The sequence is determined by DIFF (fully differential or pseudo-differential) and by the mode control bits M1 and M0 (Tables 8, 9, 10). With SCAN set, the part automatically sequences through each available channel, transmitting a single conversion result before proceeding to the next channel. The MAX1400 automatically allows sufficient time for each conversion to fully settle, to ensure optimum resolution before asserting the data-ready signal and moving to the next available channel. The scan rate is, therefore, dependent on the clock bit (CLK), the filter control bits (FS1, FS0), and the modulator frequency selection bits (MF1, MF0).

Burnout Currents

The input circuitry also provides two "burnout" currents. These small currents may be used to test the integrity of the selected transducer. They can be selectively enabled or disabled by the BOUT bit in the global setup register.

Table 12. Input Channel Configuration in Fully and Pseudo-Differential Modes (SCAN = 0)

X = Don't Care.

* *This combination is available only in pseudo-differential mode when using the internal scanning logic*

** *These combinations are only available in the calibration modes.*

External Access to Mux Outputs

The MAX1400 provides access to the switching-network output and the modulator input with the MUXOUT and ADCIN pins. This allows the user to share a single high-performance amplifier for additional signal conditioning of all input channels.

Dynamic Input Impedance at the Channel Selection Network

When used in unbuffered mode (BUFF $= 0$), the analog inputs present a dynamic load to the driving circuitry. The size of the sampling capacitor and the input sampling frequency (Figure 5) determine the dynamic load seen by the driving circuitry. The MAX1400 samples at a constant rate for all gain settings. This provides a maximum time for the input to settle at a given data rate. The dynamic load presented by the inputs varies with the gain setting. For gains of +2V/V, +4V/V, and +8V/V, the input sampling capacitor increases with the chosen gain. Gains of +16V/V, +32V/V, +64V/V, and +128V/V present the same input load as the x8 gain setting.

When designing with the MAX1400, as with any other switched-capacitor ADC input, consider the advantages and disadvantages of series input resistance. A series resistor reduces the transient-current impulse to the external driving amplifier. This improves the amplifier phase margin and reduces the possibility of ringing. The resistor spreads the transient-load current from the

Figure 5. Analog Input, Unbuffered Mode (BUFF = 0)

sampler over time due to the RC time constant of the circuit. However, an improperly chosen series resistance can hinder performance in fast 16-bit converters. The settling time of the RC network can limit the speed at which the converter can operate properly, or reduce the settling accuracy of the sampler. In practice, this means ensuring that the RC time constant—resulting from the product of the driving source impedance and the capacitance presented by both the MAX1400's input and any external capacitances—is sufficiently small to allow settling to the desired accuracy. Tables 13a–13d summarize the maximum allowable series resistance vs. external capacitance for each MAX1400 gain setting in order to ensure 16-bit performance in unbuffered mode.

Input Buffers

The MAX1400 provides a pair of input buffers to isolate the inputs from the capacitive load presented by the PGA/modulator (Figure 6). The buffers are chopper stabilized to reduce the effect of their DC offsets and lowfrequency noise. Since the buffers can represent more than 50% of the total analog power dissipation, they may be shut down in applications where minimum power dissipation is required and the capacitive input load is not a concern. Disable the buffers in applications where the inputs must operate close to AGND or V+.

When used in buffered mode, the buffers isolate the inputs from the sampling capacitors. The samplingrelated gain error is dramatically reduced in this mode. A small dynamic load remains from the chopper stabilization. The multiplexer exhibits a small input leakage current of up to 10nA. With high source resistances, this leakage current may result in a DC offset.

Table 14. REXT, CEXT Values for Less than 16-Bit Gain Error in Buffered (BUFF = 1) Mode—All Modulator Sampling Frequencies (MF1, MF0 = XX); X2CLK = 0; fCLKIN = 2.4576MHz

Reference Input

The MAX1400 is optimized for ratiometric measurements and includes a fully differential reference input. Apply the reference voltage across REFIN+ and REFIN-, ensuring that REFIN+ is more positive than REFIN-. REFIN+ and REFIN- must be between AGND and V+. The MAX1400 is specified with a +2.5V reference when operating with a $+5V$ analog supply $(V+)$.

Modulator

The MAX1400 performs analog-to-digital conversion using a single-bit, second-order, switched-capacitor modulator. A single comparator within the modulator quantizes the input signal at a much higher sample rate than the bandwidth of the signal to be converted. The quantizer then presents a stream of 1s and 0s to the digital filter for processing, to remove the frequencyshaped quantization noise.

The MAX1400 modulator provides 2nd-order frequency shaping of the quantization noise resulting from the single bit quantizer. The modulator is fully differential for maximum signal-to-noise ratio and minimum susceptibility to power-supply noise.

The modulator operates at one of a total of eight different sampling rates (f_M) determined by the master clock frequency (fCLKIN), the X2CLK bit, the CLK bit, and the modulator frequency control bits MF1 and MF0. Power dissipation is optimized for each of these modes by controlling the bias level of the modulator. Table 15 shows the input and reference sample rates.

PGA

MAX1400

DOPIXVW

A programmable gain amplifier (PGA) with a userselectable gain of x1, x2, x4, x8, x16, x32, x64, or x128 (Table 6) precedes the modulator. Figure 8 shows the default bipolar transfer function with the following illustrated codes: 1) PGA = $0.$ DAC = $0:$ 2) PGA = $3.$ DAC = 0; or 3) PGA = 3, DAC = 3.

Output Noise

Tables 16a and 16b show the rms noise for typical output frequencies (notches) and -3dB frequencies for the $MAX1400$ with $fCLKIN = 2.4576MHz$. The numbers given are for the bipolar input ranges with V_{REF} = +2.50V, with no buffer (BUFF = 0) and with the buffer inserted (BUFF $= 1$). These numbers are typical and are generated at a differential analog input voltage of 0. Figure 7 shows graphs of Effective Resolution vs. Gain and Notch Frequency. The effective resolution values were derived from the following equation:

Effective Resolution = $(SNR_{dB} - 1.76dB) / 6.02$

The maximum possible signal divided by the noise of the device, SNR_{dB} , is defined as the ratio of the input full-scale voltage (i.e., $2 \times V$ REFIN / GAIN) to the output rms noise. Note that it is not calculated using peak-topeak output noise numbers. Peak-to-peak noise numbers can be up to 6.6 times the rms numbers, while effective resolution numbers based on peak-to-peak noise can be 2.5 bits below the effective resolution based on rms noise, as quoted in the tables.

Figure 7. Effective Resolution vs. Gain and Notch Frequency

The noise shown in Table 16 is composed of device noise and quantization noise. The device noise is relatively low but becomes the limiting noise source for high gain settings. The quantization noise is determined by the notch frequency and becomes the dominant noise source as the notch frequency is increased.

Offset Correction DAC

The MAX1400 provides a coarse (3-bit plus sign) offset correction DAC at the modulator input. Use this DAC to remove the offset component in the input signal, allowing the ADC to operate on a more sensitive range. The DAC offsets up to $\pm 116.7\%$ of the selected range in $\pm 16.7\%$ increments for unipolar mode and up to $\pm 58.3\%$ of the selected range in ±8.3% increments for bipolar mode. When a DAC value of 0 is selected, the DAC is completely disconnected from the modulator inputs and does not contribute any noise. Figures 8 and 9 show the effect of the DAC codes on the input range and transfer function.

Clock Oscillator

The clock oscillator may be used with an external crystal (or resonator) connected between CLKIN and CLKOUT, or may be driven directly by an external oscillator at CLKIN with CLKOUT left unconnected. In normal operating mode, the MAX1400 is specified for operation with CLKIN at either 1.024 MHz (CLK = 0) or 2.4576 MHz (CLK = 1, default). When operated at these frequencies, the part may be programmed to produce frequency response nulls at the local line frequency (either 60Hz or 50Hz) and the associated line harmonics.

Figure 8. Effect of PGA and DAC Codes on the Bipolar Transfer Function

In standby mode (STBY $= 1$) all circuitry, with the exception of the serial interface and the clock oscillator, is powered down. The interface consumes minimal power with a static SCLK. Enter full power-down mode (including the oscillator) by setting the FULLPD bit in the special-function register. When exiting a full-power shutdown, perform a hardware reset or a software reset after the master clock signal is established (typically 10ms when using the on-board oscillator with an external crystal) to ensure that any potentially corrupted registers are cleared.

It is often helpful to use higher-frequency crystals or resonators, especially for surface-mount applications where the result may be reduced PC board area for the oscillator component and a lower price or better component availability. Also, it may be necessary to operate the part with a clock source whose duty cycle is not close to 50%. In either case, the MAX1400 can operate with a master clock frequency of up to 5MHz, and includes an internal divide-by-2 prescaler to restore the internal clock frequency to a range of up to 2.5MHz with a 50% duty cycle. To activate this prescaler, set the X2CLK bit in the control registers. Note that using CLKIN frequencies above 2.5MHz in combination with the X2CLK mode will result in a small increase in digital supply current.

MAXM

Figure 9. Input Voltage Range vs. DAC Code

Digital Filter

The on-chip digital filter processes the 1-bit data stream from the modulator using a $SINC³$ or $SINC³$ filter. The SINC filters are conceptually simple, efficient, and extremely flexible, especially where variable resolution and data rates are required. Also, the filter notch positions are easily controlled, since they are directly related to the output data rate (1 / data word period).

The $SINC¹$ function results in a faster settling response while retaining the same frequency response notches as the default $SINC³$ filter. This allows the filter to settle faster at the expense of resolution and quantization noise. The $SINC¹$ filter settles in one data word period. With 60Hz notches (60Hz data rate), the settling time would be 1 / 60Hz or 16.7ms whereas the SINC 3 filter would settle in 3 / 60Hz or 50ms. Toggle between these filter responses using the FAST bit in the global setup register. Use $SINC¹$ mode for faster settling and switch to SINC³ mode when full accuracy is required. Switch from the $SINC¹$ to $SINC³$ mode by resetting the FAST bit low. The DRDY signal will go false and will be reasserted when valid data is available, a minimum of three data-word periods later.

The digital filter can be bypassed by setting the MDOUT bit in the global setup register. When MDOUT $= 1$, the raw output of the modulator is directly available at DOUT.

Filter Characteristics

The MAX1400 digital filter implements both a $SINC¹$ (sinx/x) and SINC 3 (sinx/x)³ lowpass filter function. The transfer function for the $SINC³$ function is that of three cascaded SINC¹ filters described in the z-domain by:

$$
H(z) = \left[\frac{1}{N} \frac{1 - z^{-N}}{1 - z^{-1}}\right]^3
$$

and in the frequency domain by:

$$
H(f) = \left[\frac{1}{N} \frac{\sin\left(Np \frac{f}{f_M}\right)}{\sin\left(p \frac{f}{f_M}\right)}\right]^3
$$

where N, the decimation factor, is the ratio of the modulator frequency fm to the output frequency fn.

Figure 10 shows the filter frequency response. The SINC³ characteristic cutoff frequency is 0.262 times the first notch frequency. This results in a cutoff frequency of 15.72Hz for a first filter notch frequency of 60Hz. The response shown in Figure 10 is repeated at either side of the digital filter's sample frequency (f_M) and at either side of the related harmonics $(2f_M, 3f_M, \ldots)$.

The response of the $SINC³$ filter is similar to that of a $SINC¹$ (averaging filter) filter but with a sharper rolloff. The output data rate for the digital filter corresponds with the positioning of the first notch of the filter's frequency response. Therefore, for the plot of Figure 10 where the first notch of the filter is at 60Hz, the output data rate is 60Hz. The notches of this (sinx/x)³ filter are repeated at multiples of the first notch frequency. The $SINC³$ filter provides an attenuation of better than 100dB at these notches.

Determine the cutoff frequency of the digital filter by the value loaded into CLK, X2CLK, MF1, MF0, FS1, and FS0 in the global setup register. Programming a different cutoff frequency with FS0 and FS1 does not alter the profile of the filter response; it changes the frequency of the notches. For example, Figure 11 shows a cutoff frequency of 13.1Hz and a first notch frequency of 50Hz.

For step changes at the input, a settling time must be allowed before valid data can be read. The settling time depends upon the output data rate chosen for the filter. The settling time of the $SINC³$ filter to a full-scale step

Figure 10. Frequency Response of the SINC3 Filter (Notch at 60Hz)

/VI/IXI/VI

input can be up to four times the output data period. For a synchronized step input (using the FSYNC function or the internal scanning logic), the settling time is three-times the output data period.

Analog Filtering

The digital filter does not provide any rejection close to the harmonics of the modulator sample frequency. However, due to the high oversampling ratio of the MAX1400, these bands occupy only a small fraction of the spectrum and most broadband noise is filtered. Therefore, the analog filtering requirements in front of the MAX1400 are considerably reduced compared to a conventional converter with no on-chip filtering. In addition, because the part's common-mode rejection of 90dB extends out to several kHz, common-mode noise susceptibility in this frequency range is substantially reduced.

Depending on the application, it may be necessary to provide filtering prior to the MAX1400 to eliminate unwanted frequencies the digital filter does not reject. It may also be necessary in some applications to provide additional filtering to ensure that differential noise signals outside the frequency band of interest do not saturate the analog modulator.

If passive components are placed in front of the MAX1400, when the part is used in unbuffered mode, ensure that the source impedance is low enough not to introduce gain errors in the system. This can significantly limit the amount of passive anti-aliasing filtering that can be applied in front of the MAX1400 in unbuffered mode. However, when the part is used in buffered mode, large source impedances simply result in a small

Figure 11. Frequency Response of the SINC3 Filter (Notch at 50Hz)

DC offset error (a 1k Ω source resistance will cause an offset error of less than 10µV). Therefore, where any significant source impedances are required, Maxim recommends operating the part in buffered mode.

Calibration Channels

Two fully differential calibration channels allow measurement of the system gain and offset errors. Connect the CALOFF channel to 0V and the CALGAIN channel to the reference voltage. Average several measurements on both CALOFF and CALGAIN. Subtract the average offset code and scale to correct for the gain error. This linear calibration technique can be used to remove errors due to source impedances on the analog input (e.g., when using a simple RC anti-aliasing filter on the front end).

Applications Information

SPI Interface (68HC11, PIC16C73)

Microprocessors with a hardware SPI (serial peripheral interface) can use a 3-wire interface to the MAX1400 (Figure 12). The SPI hardware generates groups of eight pulses on SCLK, shifting data in on one pin and out on the other pin.

For best results, use a hardware interrupt to monitor the INT pin and acquire new data as soon as it is available. If hardware interrupts are not available, or if interrupt latency is longer than the selected conversion rate, use the FSYNC bit to prevent automatic measurement while reading the data output register.

The example code in Figure 13 shows how to interface with the MAX1400 using a 68HC11. System-dependent initialization code is not shown.

MAX1400

MAX1400

Bit Banging Interface (80C51, PIC16C54)

Any microcontroller can use general-purpose I/O pins to interface to the MAX1400. If a bidirectional or opendrain I/O pin is available, reduce the interface pin count by connecting DIN to DOUT (Figure 14). Figure 15 shows how to emulate the SPI in software. Use the same initialization routine shown in Figure 13.

For best results, use a hardware interrupt to monitor the INT pin and acquire new data as soon as it is available. If hardware interrupts are not available, or if interrupt latency is longer than the selected conversion rate, use the FSYNC bit to prevent automatic measurement while reading the data output register.

    -1
    return x;
```
Figure 15. Bit Banging SPI Replacement

Strain Gauge Operation

Connect the differential inputs of the MAX1400 to the bridge network of the strain gauge. In Figure 16, the analog positive supply voltage powers the bridge network and the MAX1400 along with its reference voltage. The on-chip PGA allows the MAX1400 to handle an analog input voltage range as low as 20mV full scale. The differential inputs of the part allow this analog input range to have an absolute value anywhere between AGND and V+.

Temperature Measurement

Figure 17 shows a connection from a thermocouple to the MAX1400. In this application, the MAX1400 is operated in its buffered mode to allow large decoupling capacitors on the front end. These decoupling capacitors eliminate any noise pickup form the thermocouple leads. When the MAX1400 is operated in buffered mode, it has a reduced common-mode range. In order to place the differential voltage from the thermocouple on a suitable common-mode voltage, the AIN2 input of the MAX1400 is biased at the reference voltage, +2.5V.

Figure 16. Strain-Gauge Application with MAX1400

Figure 17. Thermocouple Application with MAX1400

4–20mA Loop-Powered Transmitters

Low power, single-supply operation, and easy interfacing with optocouplers make the MAX1400 ideal for loop-powered 4–20mA transmitters. Loop-powered transmitters draw their power from the 4–20mA loop, limiting the transmitter circuitry to a current budget of 4mA. Tolerances in the loop further limit this current budget to 3.5mA. Since the MAX1400 consumes only 250µA, a total of 3.25mA remains to power the remaining transmitter circuitry. Figure 18 shows a block diagram for a loop-powered 4–20mA transmitter.

Power Supplies

No specific power sequence is required for the MAX1400; either the V+ or the V_{DD} supply can come up first. While the latchup performance of the MAX1400 is good, it is important that power be applied to the MAX1400 before the analog input signals (AIN_) or the CLKIN inputs, to avoid latchup. If this is not possible, then the current flow into any of these pins should be limited to 50mA. If separate supplies are used for the MAX1400 and the system digital circuitry, then the MAX1400 should be powered up first.

Figure 18. 4–20mA Transmitter

Grounding and Layout

For best performance, use printed circuit boards with separate analog and digital ground planes. Wire-wrap boards are not recommended.

Design the printed circuit board so that the analog and digital sections are separated and confined to different areas of the board. Join the digital and analog ground planes at only one point. If the MAX1400 is the only device requiring an AGND to DGND connection, then the ground planes should be connected at the AGND and DGND pins of the MAX1400. In systems where multiple devices require AGND to DGND connections, the connection should still be made at only one point. Make the star ground as close to the MAX1400 as possible.

Avoid running digital lines under the device, because these may couple noise onto the die. Run the analog ground plane under the MAX1400 to minimize coupling of digital noise. Make the power-supply lines to the MAX1400 as wide as possible to provide low-impedance paths and reduce the effects of glitches on the power-supply line.

Shield fast switching signals, such as clocks, with digital ground to avoid radiating noise to other sections of the board. Avoid running clock signals near the analog inputs. Avoid crossover of digital and analog signals. Traces on opposite sides of the board should run at right angles to each other. This will reduce the effects of feedthrough on the board. A microstrip technique is best, but is not always possible with double-sided boards. In this technique, the component side of the board is dedicated to ground planes while signals are placed on the solder side.

Good decoupling is important when using high-resolution ADCs. Decouple all analog supplies with 10µF tantalum capacitors in parallel with 0.1µF HF ceramic capacitors to AGND. Place these components as close to the device as possible to achieve the best decoupling.

See the MAX1402 evaluation kit manual for recommended layout. The evaluation board package includes a fully assembled and tested evaluation board.

Optical Isolation

For applications that require an optically isolated interface, refer to Figure 19. With 6N136-type optocouplers, maximum clock speed is 4MHz. Maximum clock speed is limited by the degree of mismatch between the individual optocouplers. Faster optocouplers allow faster signaling at a higher cost.

Chip Information

TRANSISTOR COUNT: 34,648 SUBSTRATE CONNECTED TO AGND

Package Information

(The package drawing(s) in this data sheet may not reflect the most current specifications. For the latest package outline information, go to **www.maxim-ic.com/packages**.)

Maxim cannot assume responsibility for use of any circuitry other than circuitry entirely embodied in a Maxim product. No circuit patent licenses are implied. Maxim reserves the right to change the circuitry and specifications without notice at any time.
