POWER SUPPLY DE-COUPLING

In a typical PCB layout for the DS21x5y, all of the VDD pins will connect to a common power plane and all the VSS lines will connect to a common ground plane. There are three recommended methods for de-coupling shown below in both schematic and pictorial form. As shown in the pictorials, the capacitors should be symmetrically located about the device. The first shown in figure 3 uses standard capacitors, two 33uf tantalums, two .33uf ceramics and two .01uf ceramics. The second method shown in figure 4 uses a single 68uf tantalum, two .33uf ceramics and two .01uf ceramics. The third method shown in figure 5 uses only four capacitors, two 1.5uf MLC and two .01uf ceramics. The 1.5uf is an MLC (Multi Layer Ceramic) type. The MLC construction is a low inductance type, which allows a smaller value of capacitance to be used. Since VDD and VSS signals will typically pass vertically to the power and ground planes of a PCB, the de-coupling caps must be placed as close to the DS21Qx5y as possible and routed vertically to power and ground planes.

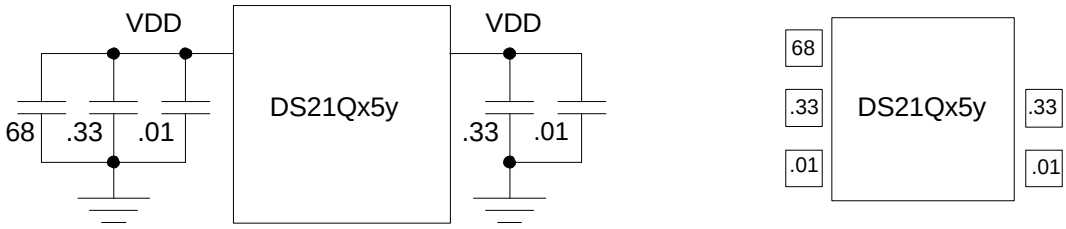
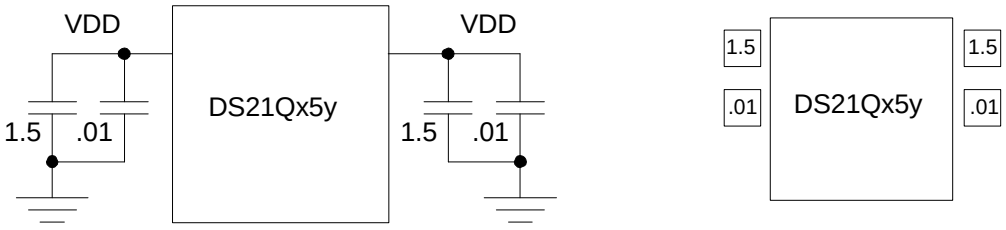
De-coupling scheme using single 68uf cap. Figure 4



De-coupling scheme using MCL caps. Figure 5



All capacitor values in figures 3, 4 and 5 are in uf.
